## General Introduction

A visualized, non-expert version of this introductory chapter can be accessed using the following QR-code or hyperlink. Both link to a 3-minute, Dutch spoken video in which I explain the background and general aim of this thesis: [Video Summary](#)

## **Memory, dementia, and Alzheimer's**

At this very moment, whilst reading this text, your body is processing a tremendous amount of information unrelated to the reading to get a sense of what is happening on the inside and outside. Although the focus may be on the visual information coming from these words, other stimuli, for example tactile information coming from holding this booklet or electronic device, is constantly being sent to the brain. The brain receives all incoming information, but only focuses on those stimuli that are deemed important. Evolutionary, it is beneficial to be able to recognize and prioritize situations or states of being, that are deemed important, in order to respond to or handle them in a manner that ensures survival and/or the production of offspring. The ability to form and store memories ensures that experiences can be 'captured' and that an individual can respond aptly to future, similar situations. One could argue that one's memory, in part, creates one's personality as it determines how someone behaves in and responds to specific similar or related situations. At the personal level, memory formation and storage allows to keep, in a literal sense, cheerful moments and loved ones in mind. If this information stays 'out of mind' ('demens' in Latin), a person may suffer from dementia. Clearly, memory impairments cause a tremendous burden on patients suffering from dementia, their family members, and caregivers.

The most common cause of dementia is Alzheimer's disease (AD). AD is associated with progressive memory impairments and is characterized by the toxic buildup and aggregation of amyloid- $\beta$  ( $A\beta$ ) and tau, the aggregates of which are referred to as plaques and tangles, respectively. While the pathological

characteristics are similar, a distinction can be made between familial and sporadic AD. Familial AD typically develops earlier in life than sporadic AD and is associated with mutations in the amyloid precursor protein (*APP*) and presenilin (*PSEN1* and *PSEN2*) genes (Bertram and Tanzi, 2008). In contrast, sporadic AD, which is more prevalent, is not associated with mutations in these genes, but can be linked to other genetic risk factors (described in detail by Bellenguez et al. (2022) and Bertram and Tanzi (2008)). Next to genetic aspects, environmental and lifestyle factors can influence the development and progression of AD (reviewed by Stozická et al. (2007)). Although the different forms of AD and the associated neuropathology can involve different underlying causal mechanisms, similar consequences are being observed within the brains of AD patients. Overall, A $\beta$  plaques and tau tangles are associated with neuro-inflammation as the brain reacts to these neurotoxic buildups with an immunological response. This inflammatory environment and the plaques and tangles themselves negatively impact neuronal function and survival and the ability of neurons and other cell types to promote (neuro)plasticity. Neuroplasticity can be described as the brain's ability to effectively respond and adapt to incoming stimuli by promoting mitosis (e.g. neurogenesis), phenotypic changes (e.g. cell differentiation), and morphological changes (e.g. the number of synaptic connections and the growth and/or extension of neuronal axons and dendrites). These neuroplasticity mechanisms are crucial for effective memory consolidation. In AD, neuroplasticity has been shown to be impaired as AD brains exhibit neurodegeneration and neurons with less complex morphologies (Teter and Ashford, 2002). It has been widely found that A $\beta$  exposure reduces neurite outgrowth in cell culture experiments, which indicates the direct effect of AD pathology on neuronal morphology (e.g. (Kwon et al., 2010)). Neurite outgrowth is just one process that is affected in AD, but also the number of dendrites, dendritic length, and dendritic spine density have been found to be reduced by A $\beta$  exposure (Cui et al., 2019).

As AD progresses, the pathological A $\beta$  plaques and tau tangles become more abundant and widespread throughout the brain causing increased neuro-inflammation and impaired neuroplasticity (Braak and Braak, 1991). Brain regions important in memory functioning (e.g. the basal forebrain and hippocampus) appear to be particularly sensitive to AD-associated pathology (Brueggen et al., 2015; Schmitz et al., 2016). The hippocampus is a crucial brain structure in consolidating information in long-term memory. In addition, the basal forebrain signals to the hippocampus using the neurotransmitter acetylcholine to facilitate memory consolidation. Hence, degeneration of both the basal forebrain and hippocampus in response to AD-associated pathology has detrimental effects on the ability to store memories.

Based on the rationale that acetylcholine signaling from the basal forebrain is diminished in AD, several types of medication have been developed in an effort to compensate for decreased cholinergic signaling. At the time of writing, five molecules have been approved for the treatment of AD: donepezil, rivastigmine, galantamine, memantine, and (in the United States only) aducanumab. The first three molecules belong to the class of acetylcholinesterase inhibitors (AChEI) and increase cholinergic signaling by inhibiting the enzymatic breakdown of acetylcholine. Memantine blocks the N-methyl-D-aspartate (NMDA) receptor and thereby can reduce neurotoxicity by preventing 'overexcitation' of neurons that may be caused by an imbalanced excitatory/inhibitory neuron ratio. Noteworthy, memantine has also been reported to block specific acetylcholine receptors (i.e.  $\alpha 7$  nicotinic acetylcholine receptors) (Aracava et al., 2005), which is a mechanism that can also promote memory-enhancing effects as reported by myself and my research group, and others in cell and animal studies (Hahn et al., 2011; van Goethem et al., 2019). Aducanumab, which has only recently been approved by the Food and Drug Administration (FDA), yet rejected by the European Medicines Agency (EMA), has been developed to reduce A $\beta$  plaques in the brain, but its clinical efficacy and safety

are, despite its approval, still under debate (Sevigny et al., 2016). Clearly, functional memory improvements of current AD medication are only modest and often associated with severe side effects, e.g. diarrhea (AChEI), obstipation (memantine), nausea and vomiting (AChI and memantine), or brain swelling and brain bleeding (aducanumab) (Casey et al., 2010; Seibert et al., 2021). Hence, novel approaches are crucial for efficacious and safe treatment of memory impairments in AD.

### **‘Memory molecules’**

To facilitate the discovery and development of new pharmacological compounds, understanding the molecular signaling cascades underlying memory consolidation is essential. In other words, which molecules are important for memory formation? Fundamental insights into these ‘memory molecules’ have been gathered through the seminal work of Eric Kandel and Paul Greengard (Kandel, 2012; Walaas and Greengard, 1991). It has now been well-established that upon binding of neurotransmitters, specific signaling cascades can be initiated in neurons. Many of these cascades, including those elicited by cholinergic signaling, involve the conversion of adenosine triphosphate (ATP) into the signaling molecule cyclic adenosine monophosphate (cAMP) by the enzyme adenylate cyclase (AC). cAMP can then activate, among other molecules, protein kinase A (PKA), which by itself can induce changes by phosphorylating target proteins. For example, phosphorylation by PKA can lead to sensitization of neurotransmitter receptors, which facilitates the connectivity between two neurons. Particularly important for long-term memory formation is PKA-mediated phosphorylation of the transcription factor cAMP response element-binding protein (CREB) (Kandel, 2012). Upon its phosphorylation, CREB induces the transcription of several genes that promote neuroplasticity. Through these transcription-dependent mechanisms, several changes that strengthen synaptic connections between neurons are being induced. These changes comprise, for example, physiological changes owing to the synthesis

of neurotransmitter receptors and morphological changes via the formation of axons and dendrites.

Thus, the cAMP-PKA-CREB signaling cascade is of utmost important for functional memory consolidation. This notion is also supported by the observation that cAMP-PKA-CREB signaling is decreased in AD (reviewed in: (Kelly, 2018)). As such, pharmacological modulation of this pathway provides opportunities to restore memory functioning in AD. While the synthesis of cAMP occurs specifically by AC, its hydrolytic degradation is regulated exclusively via members of the superfamily of phosphodiesterase (PDE) enzymes. Hence, these PDEs provide interesting targets to specifically modulate cAMP levels and associated signaling.

The PDE superfamily consists of 11 gene families (PDE1-PDE11), which are categorized based on functional protein domains and substrate selectivity (Baillie et al., 2019; Bender and Beavo, 2006; Chapter 2: Paes et al., 2021). Next to hydrolyzing cAMP, certain members of the PDE enzyme family degrade the closely related cyclic guanosine monophosphate (cGMP). In fact, the gene families PDE1, PDE2, PDE3, PDE10, and PDE11 can degrade both cAMP and cGMP. PDE5, PDE6, and PDE9 specifically break down cGMP, whilst PDE4, PDE7, and PDE8 are selective towards cAMP. Given the importance of cAMP in memory consolidation signaling, the cAMP-selective PDE families are interesting targets to modulate this signaling. By inhibiting these PDE enzymes in the brain, cAMP degradation can be diminished, leading to stimulation of memory consolidation processes.

## **PDE4 enzymes and PDE4-macology**

Historically, most research has been conducted on the PDE4 family, as for a long time, no selective PDE7 and PDE8 inhibitors were available. In studies as early as in 1976, the archetypical PDE4 inhibitor rolipram was used to identify and inhibit cAMP-specific PDE activity (Schwabe et al., 1976). Rolipram was also found to be able to inhibit activity of the *Drosophila* enzyme encoded by the *dunce* gene, which plays

a pivotal role in learning and memory (Davis et al., 1989; Dudai, 1988). Subsequently, rolipram-sensitive PDE4 enzyme orthologues of *dunce* were discovered in rats and humans and observed to be expressed in brain tissue (Bolger et al., 1993; Davis et al., 1989; Schwabe et al., 1976; Swinnen et al., 1989a; b). These findings, together with clinical studies using rolipram as a potential antidepressant, strongly suggested that PDE4 inhibition has effects in the mammalian brain. Accordingly, several studies found that PDE4 inhibition is able to preserve intact memory and restore impaired memory in rodents (Egawa et al., 1997; Rutten et al., 2007; Vanmierlo et al., 2016). In addition, PDE4 inhibition has been shown to reduce neuroinflammation and protect against neuronal death (Pearse and Hughes, 2016; Vilhena et al., 2021). As both neuroinflammation and neuronal death are hallmarks of AD, PDE4 inhibitors are promising candidates to prevent, slow down or halt the progression of AD (Guerriero et al., 2017).

Consequently, the therapeutic potential of PDE4 inhibition to treat AD has been examined in preclinical studies. In different animal models of AD, inhibition of PDE4 was found to restore neuroplasticity, reduce neuroinflammation and/or improve memory performance (Gong et al., 2004; Guo et al., 2017; Shi et al., 2021; Vitolo et al., 2002; Zhang et al., 2004). Furthermore, the PDE4 inhibitor roflumilast was found to enhance verbal learning in both young and old healthy individuals (Blokland et al., 2019; Van Duinen et al., 2018). Despite these beneficial effects, clinical use of PDE4 inhibitors has been hampered so far due to the occurrence of adverse side effects including nausea, emesis, headache, and diarrhea (Compton et al., 2001). PDE4 enzymes, as pivotal regulators of cAMP signaling, are expressed in many organs and in different cell types, which can produce unwanted effects additional to the therapeutic actions in the brain. Hence, PDE4 inhibition as a therapeutic strategy should be optimized in order to improve efficacy and safety.

## The memory-modulating PDE4D subtype

The PDE4 gene family comprises multiple members. Four different PDE4 genes exist (PDE4A-D). These various genes encode subtypes of PDE4 enzymes with distinct amino acid sequences (Bolger et al., 1993; Bolger, 1994; Johnson et al., 2010; Milatovich et al., 1994). Hence, targeting specific PDE4 subtypes may provide a promising opportunity to enhance memory functioning while minimizing or preventing side effects. Using PDE4 subtype-selective inhibitors, Zhang et al. identified that inhibition of PDE4D, rather than PDE4B, displayed most potent memory-enhancing effects in rodents (Zhang et al., 2017). Additional support for a role of PDE4D in cognition has been provided by the fact that mutations in PDE4D are associated with the neurodevelopmental disorder acrodysostosis (Lee et al., 2012). Moreover, genetic variation in the *PDE4D* gene has been associated with human cognitive performance (Gurney, 2019). In addition, expression of PDE4D was found to correlate negatively with cognitive performance in an aging study using monozygotic twins (Mohammadnejad et al., 2021). In patients suffering from mild cognitive impairment and AD, polymorphisms in the *PDE4D* gene were found to affect the functional network brain activity (Xiang et al., 2020).

Thus, given its involvement in cognition, PDE4D may provide a more specific target for pharmacological interventions to treat memory problems in AD. As a result, efforts have been made to develop PDE4D-selective inhibitors, which show pro-cognitive effects in animal studies (Brullo et al., 2016; Bruno et al., 2011; Bruno et al., 2009; Burgin et al., 2010; Ricciarelli et al., 2017; Sierksma et al., 2014; Wang et al., 2020; Zhang et al., 2018). Despite the efficacy of PDE4D-selective inhibition, PDE4D inhibition seems to induce emetic side effects elicited through  $\alpha_2$ -adrenoceptor-mediated mechanisms in the brainstem, which would hamper their clinical use (Robichaud et al., 2001; Robichaud et al., 2002). Recently, studies by the Richter laboratory have indicated that other side effects observed upon PDE4 inhibition (i.e. hypothermia and gastroparesis) are not predominantly mediated by PDE4D but are

rather a result of inhibition or more than one PDE4 subtype (Boyd et al., 2021; McDonough et al., 2020a; McDonough et al., 2020b). Thus, compared to the complete side effect profile of non-specific PDE4 inhibitors, PDE4D selective inhibitors may show fewer or less intense side effects. Indeed, certain PDE4D inhibitors have shown to be less emetic than non-specific PDE4 inhibitors (Bruno et al., 2011; Ricciarelli et al., 2017; Zhang et al., 2018), which may be a result of the fact that the PDE4D-selective inhibition elicits effects in the brainstem (emesis) but does not impact the stomach (gastroparesis). However, considering the role of PDE4D in brainstem-mediated emetic side effects, these side effects may have to be prevented or circumvented in order to fully exploit PDE4D inhibition as a safe and efficacious treatment strategy to ameliorate memory problems in AD.

## **The importance of isoforms**

Interestingly, the *PDE4D* gene encodes different transcript variants that translate into different protein isoforms. As PDE4D subtypes and isoforms are expressed in a tissue-dependent and cell-type-specific manner (Miró et al., 2002a; Miró et al., 2002b; Pérez-Torres et al., 2000), inhibition of specific isoforms can produce different physiological and/or behavioral effects. Hence, inhibition of specific PDE4D isoforms may produce memory-enhancing effects while minimizing adverse PDE4-mediated side effects.

Although it has been well-established that different PDE4 subtypes and isoforms are cell-type specifically expressed and localize to specific intracellular compartments (Blackman et al., 2011), the role of specific PDE4D isoforms in memory processes has only sporadically been described. One study using very few samples has reported PDE4D isoform expression in post-mortem brain material of AD patients and healthy individuals (McLachlan et al., 2007). Another study found no difference in PDE4D expression in brain material of AD patients and controls, but in this study the expression of the individual PDE4D isoforms was not specified (Ugarte

et al., 2015). Therefore, it remains unknown which isoforms are important for memory processes and would thus be appropriate targets for the treatment of memory problems associated with AD. Identification of the PDE4D isoforms involved in memory processes (in AD) will allow for target specification so that treatment efficacy can be maintained whilst minimizing side effects.

Alternatively, approaches to reduce the therapeutic dose of PDE4(D) inhibitors will decrease the risk of PDE4-mediated adverse side effects. Given the fact that multiple PDE gene families can degrade cAMP and that they localize to specific intracellular compartments, inhibition of PDE4(D) and other cAMP-degrading PDEs can have synergistic effects. Using this synergistic treatment, the therapeutic dose of PDE4(D) could be lowered, which would reduce the occurrence of possible side effects.

## **Goals and outline of the thesis**

With the purpose of finding new treatment strategies to efficaciously and safely inhibit PDE4(D), in order to stimulate memory consolidation processes as a treatment for AD, the goals of this thesis are:

- To identify which PDE4D isoforms are involved in neuroplasticity processes that are impaired by AD-associated pathology
- To investigate the therapeutic potential of using combined treatments to reduce the therapeutic dose of PDE4(D) inhibitors

By means of literature research and *in vivo*, *in vitro*, and *in silico* experimental approaches, these goals were pursued as outlined in the following chapters.

**Chapter 2** provides a comprehensive review on a myriad of aspects of PDE4 enzymes as pharmacological targets. Firstly, all currently known PDE4 subtypes,

transcript variants, and isoforms in humans and rodents are defined. To determine which PDE4(D) isoform should be picked as optimal therapeutic target in AD, an understanding those PDE4(D) isoforms existing is crucial. Both in the scientific literature and in online databases, inconsistencies in classification appear. Specifically, mRNA molecules that are different in sequence, but stem from the same gene would be referred to as transcript variants. As these different mRNA species differ in sequence, they can encode for protein products with distinct amino acid sequences that would be referred to as (protein) isoforms. Difficulties arise in classifying and comparing these transcript variants and isoforms as online databases (e.g. Ensembl and NCBI Gene) use different annotations. Additional discrepancies exist in the naming of orthologues across species (e.g. the rodent equivalents of human PDE4A isoforms are named differently). Hence, it is crucial to have a proper understanding of how the four distinct PDE4 genes encode the different transcript variants that translate to different protein isoforms for different species. The obtained understanding of PDE4D gene, mRNA, and protein sequences is critical for translational experiments described in **Chapter 3** and **Chapter 4**. Secondly, the effects of inherent, structural features of the different PDE4 isoforms on their enzymatic activity are being described. Furthermore, per isoform, the consequences of post-translational modifications and their interactions with other proteins, on enzyme activity and inhibitor binding are outlined. Specific post-translational modifications are investigated *in silico* in more detail in **Chapter 5**. This information is followed up by a detailed description of a large list of PDE4 inhibitors and their affinity for PDE4 subtypes, isoforms, and conformations. Insights acquired from this overview are then discussed in light of PDE4 inhibitor screening pipelines and are used to better put preclinical findings into context in **Chapter 6**. Next, strategies for target specification and approaches to develop subtype- and isoform-specific PDE4 inhibitors are described. Lastly, PDE4 inhibitors are compared regarding their ability

to elicit side effects and potential molecular mechanisms underlying these side effects are pointed out.

**Chapter 3** presents an experimental study that investigated which PDE4D isoforms display altered transcriptional regulation in AD and may therefore be (more) suitable therapeutic targets. In this study, human post-mortem temporal lobe brain material of AD patients and healthy controls is used, in which the epigenetic signature of the *PDE4D* gene is measured. In addition, mRNA expression levels of PDE4D isoforms are determined. Both the epigenetic and transcriptional profiles are correlated with the degrees of AD-associated pathology in the tissue and the subject's degree of cognitive decline.

Complementing and following up on the previous chapter, **Chapter 4** demonstrates a series of experiments in which PDE4D isoform expression changes are determined in the hippocampus and frontal cortex of transgenic AD mice. Furthermore, the effects of pharmacological PDE4D inhibition on neurite outgrowth of neuronal cells in both the presence and absence of amyloid- $\beta$  are described. Most importantly, the potential of PDE4D isoform-specific inhibition targeted at facilitating neurite outgrowth and protecting against amyloid- $\beta$  is examined by means of *in vitro* CRISPR-Cas9-mediated knockout experiments.

In **Chapter 5**, a computational model of PDE4 isoform-mediated cAMP signaling is presented. The model was used to simulate how different PDE4 isoforms dynamically control cAMP levels and downstream signaling over time. By implementing isoform-specific feedback mechanisms (as also reviewed in **Chapter 2**), the importance of specific PDE4 isoform types in cAMP regulation is being highlighted.

Beyond the context of AD and as an alternative to increasing treatment-specificity by targeting PDE4D isoforms, **Chapter 6** presents the potential of combined PDE2-PDE4 inhibition to promote neuroplasticity processes *in vitro* and enhance memory consolidation *in vivo*. It is revealed that PDE2 and PDE4 inhibitors

work synergistically, thereby requiring lower doses of each, which likely minimizes the occurrence of adverse side effects.

In the concluding **Chapter 7**, the acquired insights from the previous chapters are being put into perspective, considering experimental strengths and limitations. Ultimately, an outlook is provided for future research to be explored in order to eventually let AD patients benefit from efficacious and safe (isoform-specific) PDE4(D) inhibitors.

# Chapter 2

## **The molecular biology of PDE4 enzymes as pharmacological targets:**

An interplay of isoforms, conformational states,  
and inhibitors

Published as:

Paes et al. (2021) *Pharmacol Rev.* Jul;73(3):1016-1049.  
doi: [10.1124/pharmrev.120.000273](https://doi.org/10.1124/pharmrev.120.000273)

## **LIST OF NONSTANDARD ABBREVIATIONS:**

3'UTR – 3' untranslated region

5'UTR – 5' untranslated region

5HT4 – 5-hydroxytryptamine 4

ADPKD – autosomal dominant polycystic kidney disease

AIP – aryl hydrocarbon receptor-interacting protein

AKA – also known as

AKAP – A-kinase anchoring protein

AMPK – AMP-activated protein kinase

AP – area postrema

ATF4 – activating transcription factor 4

CaMKII – calcium/calmodulin-dependent kinase II

cAMP – cyclic adenosine monophosphate

cat dom – catalytic domain

CDK5 – cyclin-dependent kinase 5

CK1 – casein kinase I

CREB – cAMP-response element binding protein

CRISPR – clustered regularly interspaced short palindromic repeats

DISC1 – disrupted in schizophrenia 1

ERK – extracellular signal-regulated kinase

GSK3 $\beta$  – glycogen synthase kinase 3 $\beta$

HARBS – high-affinity rolipram binding site

HCN – hyperpolarized cyclic nucleotide-gated channel

HSP20 – heat-shock protein 20

IC50 – half-maximum inhibitory concentration

IG – intragastric

IP – intraperitoneal

IV – intravenous

JNK – c-Jun N-terminal kinase  
LARBS – low-affinity rolipram binding site  
LR1 – linker region 1  
LR2 – linker region 2  
Mdm2 – Mouse double minute 2 homolog  
MITF – melanocyte inducing transcription factor  
MK2 – MAPK-activated protein kinase 2  
N-term – N-terminus  
NTS – nucleus tractus solitaries  
PDE – phosphodiesterase  
PHD2 – prolyl hydroxylase domain-containing protein 2  
PKA – protein kinase A  
PO – per os  
RACK1 – receptor of activated protein C kinase 1  
RyR – ryanodine receptor  
SC – subcutaneous  
SH3 – SRC Homology 3 Domain  
Shank2 – SH3 and multiple ankyrin repeat domains protein 2  
shRNA – short-hairpin RNA  
SIK1 – salt-inducible kinase 1  
SQSTM1 – Sequestosome 1  
UCR1 – upstream conserved region 1  
UCR2 – upstream conserved region 2  
XAP – HBV X-associated protein 2

## CHAPTER 2: TABLE OF CONTENTS

<b>Abstract</b> .....	34
<b>I. PDE4 subtypes and isoforms</b> .....	38
<b>II. PDE4 modifications and interactions</b> .....	48
A. UCR1-UCR2 module, dimerization, and phosphorylation .....	48
B. Phosphorylation at sites other than UCR1 .....	52
C. Indirect regulation of PDE4 activity and interactions .....	56
D. Conformational states impacting upon PDE4 activity and inhibitor binding ...	58
E. Intracellular PDE4 localization and anchoring.....	61
1. A-kinase anchoring proteins (AKAPs).....	62

## **ABSTRACT**

The phosphodiesterase 4 (PDE4) enzyme family plays a pivotal role in regulating levels of the second messenger cyclic AMP (cAMP). Consequently, PDE4 inhibitors have been investigated as a therapeutic strategy to enhance cAMP signaling in a broad range of diseases, including several types of cancers, as well as in various neurological, dermatological and inflammatory diseases. Despite their widespread therapeutic potential, the progression of PDE4 inhibitors into the clinic has been hampered due to their related relatively small therapeutic window, which increases the chance of producing adverse side effects. Interestingly, the PDE4 enzyme family consists of several subtypes and isoforms, which can be modified post-translationally or can engage in specific protein-protein interactions to yield a variety of conformational states. Inhibition of specific PDE4 subtypes, isoforms, or conformational states may lead to more precise effects and hence improve the safety profile of PDE4 inhibition. In this review, we provide an overview of the variety of PDE4 isoforms and how their activity and inhibition is influenced by post-translational modifications and interactions with partner proteins. Furthermore, we describe the importance of screening potential PDE4 inhibitors in view of different PDE4 subtypes, isoforms, and conformational states rather than testing compounds directed towards a specific PDE4 catalytic domain. Lastly, potential mechanisms underlying PDE4-mediated adverse effects are outlined. In this review, we illustrate that PDE4 inhibitors retain their therapeutic potential in a myriad of diseases, but target identification should be more precise to establish selective inhibition of disease-affected PDE4 isoforms while avoiding isoforms involved in adverse effects.

## **SIGNIFICANCE STATEMENT**

Although the PDE4 enzyme family is a therapeutic target in an extensive range of disorders, clinical use of PDE4 inhibitors has been hindered due to adverse side effects. Here, we elaborately show that safer and more effective PDE4 targeting is possible by characterizing 1) which PDE4 subtypes and isoforms exist, 2) how PDE4 isoforms can adopt specific conformations upon post-translational modifications and protein-protein interactions, and 3) which PDE4 inhibitors can selectively bind specific PDE4 subtypes, isoforms and/or conformations.

## INTRODUCTION

Since the discovery of cyclic AMP (cAMP) as a second messenger by Sutherland and Rall in 1958, its role in a wide variety of cellular processes, bodily functions, and pathologies has been thoroughly studied (Rall and Sutherland, 1958; Sutherland and Rall, 1958). Upon diverse extra- and intracellular cues, the second messenger cAMP is synthesized by adenylyl cyclases to relay signaling to adaptive changes in the cell. This notion indicates that cAMP is used as a single generic signaling molecule to convey and amplify information from different sources; a notion supported by the principle that evolution promotes utilizing the same machinery for different functions (Purvis and Lahav, 2013). Through precise regulation of the localization, abundance, and dynamics of cAMP, different signaling modes can be generated using the same generic molecule. Consequently, slight disturbances in cAMP regulation could promote pathophysiology in different cell types. Levels of cAMP are predominantly controlled through exclusive breakdown by the 3',5'-cyclic nucleotide phosphodiesterase (PDE) enzyme family. This PDE enzyme family comprises 11 gene families (PDE1-11) which display different selectivity towards their substrates cAMP and cyclic GMP (cGMP). PDE4, PDE7 and PDE8 are cAMP-selective, whilst PDE5, PDE6 and PDE9 selectively degrade cGMP. The other gene families, PDE1, -2, -3, -10 and -11 can hydrolyze both cAMP and cGMP (Beavo, 1995; Bender and Beavo, 2006). PDE4 enzymes comprise a majority of cAMP-selective PDEs in different organs and cell types (Baillie et al., 2019; Lakics et al., 2010). Hence, PDE4 enzymes are interesting pharmacological targets to specifically modulate cAMP signalling. Hence, inhibition of PDE4 has been and is clinically investigated as a therapeutic strategy in a multitude of disease areas, as also recently reviewed (Peng et al., 2020), including cognitive and affective disorders (e.g. Alzheimer's disease [NCT03817684], Fragile X syndrome [NCT03569631], schizophrenia [NCT02539550], depression (Hebenstreit et al., 1989), substance dependency [NCT03489850]), autoimmune disorders (e.g. multiple sclerosis

[NCT01982942] (Scheppers et al., 2019), rheumatoid arthritis, atopic dermatitis, Behçet syndrome [NCT02307513]), respiratory system diseases (e.g. chronic obstructive pulmonary disease and asthma (Lipworth, 2005)), dermatological conditions (e.g. psoriasis [NCT03022617]), and cancer (e.g. glioblastoma [NCT03782415]).

Although inhibition of PDE4 shows widespread therapeutic potential in preclinical research, the progression of PDE4 inhibitors into the clinic has been held back by severe adverse effects including headaches, diarrhea, dizziness, nausea and vomiting (Spina, 2008). In fact, only three PDE4 inhibitors made it to the market due to their limited or reduced adverse effects, including roflumilast (Daliresp, Daxas), apremilast (Otezla) and crisaborole (Eucrisa), for chronic obstructive pulmonary disease, psoriasis, and moderate atopic dermatitis, respectively (Baillie et al., 2019). Interestingly, the *PDE4* gene family consists of four paralogous genes which, correspondingly, encode PDE4 subtypes (i.e. PDE4A-D). Each of these genes generates a variety of transcript variants that translate into different protein isoforms (e.g. PDE4D1-9). As these PDE4 subtypes and isoforms show tissue- and cell type-specific expression and intracellular compartmentalization patterns (Houslay, 2010)(reviewed in: (Baillie et al., 2019)), more selective inhibition could reduce the abovementioned adverse effects while maintaining treatment efficacy. An additional layer of complexity is added by the fact that PDE4 enzymes can adopt different conformational states as a result of various post-translational modifications and interactions with partner proteins. Consequently, this allows for more selective targeting as PDE4 inhibitors will likely display different affinities towards different PDE4 subtypes, isoforms, and conformational states.

This review aims to provide an overview of the variety of PDE4 subtypes and isoforms, and the mechanisms by which their cellular activity and inhibitor affinity is regulated through post-translational modifications and protein-protein interactions. Moreover, current advancements and strategies towards the development of PDE4 subtype- and/or conformation-specific compounds are discussed. Lastly, several

mechanisms that potentially contribute to adverse side effect profiles of PDE4 inhibition are outlined in order to support the development of new, more specific and safer PDE4-directed therapeutics.

## I. PDE4 SUBTYPES AND ISOFORMS

Before the identification of the responsible enzymes, in 1987, rolipram was shown to inhibit cAMP-specific PDE activity (Reeves et al., 1987). As this activity was distinct from three other types of PDE activity already known at the time, it was coined PDE IV. In retrospect, earlier studies had already identified rolipram-sensitive PDE activity to be present in rat brain material and to be involved in gastric secretion (Puurunen et al., 1978; Schwabe et al., 1976). A rat orthologue of the *Drosophila* cAMP-PDE enzyme, encoded by the *dunce* gene, was found to produce an enzyme that can be inhibited by rolipram (Davis et al., 1989; Swinnen et al., 1989a; b).

In mammals, four PDE4 genes can be distinguished, all of which show similar and evolutionarily conserved exon compositions, encoding the abovementioned PDE4 subtypes PDE4A, B, C, and D (Bolger et al., 1993; Bolger, 1994; Johnson et al., 2010; Milatovich et al., 1994). Across species and among genes, there is particular sequence similarity in specific exons that encode the enzyme's catalytic domain and two regulatory domains, upstream conserved region 1 and 2 (UCR1 and UCR2). Next to their sensitivity to rolipram, PDE4 enzymes can be distinguished from other PDEs by the presence of these UCR1 and UCR2 domains. Apart from the UCR1, UCR2 and catalytic domains, the amino acid sequences of human PDE4 subtypes differ notably in the linker region 1 (LR1, between UCR1 and UCR2), LR2 (between UCR2 and catalytic domain) and the C-terminals. These differences allow for subtype-specific modulation while maintaining core PDE4 regulation and functionality as discussed in the section **PDE4 modification and interactions**.

Additional diversity is achieved at the gene level as each of the PDE4 genes contains alternative promoters that can generate distinct transcript variants by

incorporating unique exons and through recursive splicing mechanisms (Sibley et al., 2015). Different promoters may contain distinct transcription response elements that allow for transcriptional regulation associated with a diversity of signaling pathways. For example, specific promoters of the *PDE4D* gene have been identified to contain regulatory elements for the transcription factors cAMP-response element binding protein (CREB) (D'Sa et al., 2002; Le Jeune et al., 2002; Vicini and Conti, 1997), melanocyte inducing transcription factor (MITF) (Khaled et al., 2010) or activating transcription factor 4 (ATF4) (Soda et al., 2013). These transcriptional control mechanisms allow for intricate transcriptional feedback loops that upregulate PDE4 expression in order to terminate cAMP signaling associated with particular cascades. The activity of certain promoters is thus regulated by the presence of the various transcription factors, while the accessibility of the promoter may also be subject to epigenetic regulation. Indeed, epigenetic alterations at the level of DNA (hydroxy)methylation and histone modifications of the *PDE4D* gene have been associated with changes in expression on specific transcript variants (Paes et al., 2020a; Tilley and Maurice, 2005). Although the exact responsiveness of the different PDE4 promoters remains to be explored further, prior findings already suggest that PDE4 transcription can be regulated in an intricately regulated manner enabling organ- and cell-specific expression patterns.

Depending on the location of the promoter, PDE4 mRNA transcripts will include the exons encoding both UCR1 and UCR2, only UCR2, a truncated UCR2, or only exons that encode a part of the catalytic domain (Johnston et al., 2004; Nemoz et al., 1996). Based on the presence of these UCRs, the protein products of these transcripts can be categorized as long, short, and supershort isoforms, respectively. Transcripts encoding catalytically inactive isoforms are called dead-short (Houslay, 2001). Based on deletion mutant studies, the UCR domains were found to regulate catalytic activity showing differential enzymatic kinetics for the different isoform categories (Jacobitz et al., 1996; Saldou et al., 1998). Via alternative promoters and

alternative splicing mechanisms, more than 20 human PDE4 transcript variants have been identified, allowing for tissue- and cell-specific expression regulation.

**Figure 1. Exon composition per human PDE4 transcript variant.** For each of the PDE4 genes (PDE4A-D), the exon composition is shown per transcript variant. Gray boxes depict exons and their nucleotide length. The protein isoform names and associated amino acid (aa) number per transcript are shown on the left. Start and stop codons are indicated by arrows and pins, respectively. The regions translating into UCR1, UCR2 and the catalytic domain are visualized by thick horizontal bars. \*: as the transcripts PDE4DN1-3 have only been identified on the mRNA level, amino acids lengths are isoform categories are predictions based on in-frame stop codons. This figure was established through analysis and cross-referencing of online databases (NCBI: <https://www.ncbi.nlm.nih.gov/gene> and Ensembl: <http://www.ensembl.org/index.html>) and original cloning studies (see references to studies per transcript variant in **Section PDE4 subtypes and isoforms**). An overview indicating which transcripts have counterparts in rodents or are only found in rodents is provided in the **Supplementary Material**.

## PDE4 exon composition per transcript variant

**Figure 1** highlights the exon composition per human PDE4 transcript. As described below, certain PDE4 transcripts have been identified or characterized in humans or rodents only; **Supplementary Table 1** provides an overview of which PDE4 transcript has been described per species. Human *PDE4A* encodes four long isoforms (PDE4A8 (Mackenzie et al., 2008), PDE4A4 which is named PDE4A5 in rodents (Bolger et al., 1993; Naro et al., 1996), PDE4A11 (Wallace et al., 2005), and PDE4A10 (Rena et al., 2001)), one supershort isoform (PDE4A1 (Sullivan et al., 1998)) and a dead-short, catalytically inactive, isoform (PDE4A7 (Johnston et al., 2004)) (**Supplementary Table 1**),

For human PDE4B, two long (PDE4B1 (Bolger et al., 1993) and PDE4B3 (Huston et al., 1997)), one short (PDE4B2 (McLaughlin et al., 1993)) and one supershort isoform (PDE4B5 (Cheung et al., 2007)) have been identified. In rodents, in addition, a long PDE4B4 isoform has been characterized, which was suggested to have no functional equivalent in humans due to in-frame stop codons (Shepherd et al., 2003). However, PDE4B antibodies can clearly detect an 85 kDa PDE4B species in human brain tissue corresponding to rodent PDE4B4, but the exact sequence remains to be determined (Fatemi et al., 2008) (**Supplementary Table 1**).

The least well-characterized PDE4 subtype is PDE4C which comprises three long isoforms (PDE4C1 (Engels et al., 1995), PDE4C2 (Owens et al., 1997b), and PDE4C3 (Oberholte et al., 1997)), but likely generates additional variants through complex alternative splicing (Oberholte et al., 1997). Interestingly, despite relatively little insight into its function, several studies found that the DNA methylation signature of the *PDE4C* gene correlated with aging (e.g. (Marquez-Ruiz et al., 2020)).

Lastly, the human *PDE4D* gene produces the highest number of isoforms, i.e. six long isoforms (PDE4D3, PDE4D4, PDE4D5 (Bolger et al., 1997), PDE4D7, PDE4D8 (Wang et al., 2003), PDE4D9 (Gretarsdottir et al., 2003)), one short isoform (PDE4D1 (Bolger et al., 1997)) and two supershort isoforms (PDE4D2 (Bolger et al., 1997) and PDE4D6 (Wang et al., 2003)) (**Supplementary Table 1**).

Moreover, alternatively spliced transcripts have been described for PDE4D3, -D4 and -D5 that do not translate the catalytic domain due to in-frame stop codons caused by exon deletions or insertions (**Figure 1**) (Miro et al., 2000). These variations of the 'conventional' PDE4D3, -D4, and -D5 isoforms have been respectively coined PDE4DN1, PDE4DN2, and PDE4DN3 and can be categorized as dead-short forms based on the absence of the catalytic domain. For PDE4DN1, all exons encoding UCR1 are skipped, creating a transcript that encodes the unique N-terminal of PDE4D3 followed by 31 frame-shifted codons of the UCR2 (**Figure 1**). Based on this sequence, PDE4DN1 may engage in similar protein-protein interactions as PDE4D3 would using its N-terminal residues, but the exact functional role of PDE4DN1 remains undetermined (see also section **PDE4 modifications and interactions** and **Figure 2**). In contrast to PDE4DN1, PDE4DN2 and PDE4DN3 do incorporate the UCR1-encoding exons in their transcripts (**Figure 1**). Similar to PDE4DN1, the unique N-termini as also present in PDE4D4 and PDE4D5 may allow PDE4DN2 and PDE4DN3 to bind specific protein partners or putatively cause competitive binding for these binding sites with full-length PDE4D4 and PDE4D5, respectively. This competitive binding may subsequently induce altered distribution of full-length PDE4 forms causing distinct cellular cAMP dynamics. Intriguingly, the presence of UCR1 in these truncated forms may have functional consequences on full-length PDE4 forms. It has been demonstrated that a peptide fragment of the UCR1 can bind and activate full-length long PDE4 forms (Wang et al., 2015). PDE4DN2 and PDE4DN3, containing the same sequence as this peptide fragment, may exert similar actions and could biologically be relevant by providing an additional mechanism to elevate cellular PDE4 activity. The existence of these truncated forms at the protein level and their putative activating effects on full-length long PDE4D forms, however, remain to be validated.

Importantly, the existence of these truncated PDE4DN1-3 forms has a practical consequence for quantitative PCR (qPCR) measurements. Isoform-specific

PDE4D expression can be measured using qPCR primers that amplify part of the sequence of the isoform-unique exon (and the first UCR1 exon), but in case of PDE4D4 and PDE4D5 also the respective expression of PDE4DN2 and PDE4DN3 will be detected by qPCR. Hence, PCR and gel electrophoresis should be performed in parallel using appropriate primers to determine whether expression changes are found for both the full-length and truncated transcript or for only one of these transcripts.

Recently, it has been described that *PDE4D* also encodes a highly stable, mainly cytoplasmic, circular RNA, circPDE4D, which is formed through circularization of exons 2-5 of the *PDE4D* gene (**Figure 1**) (Wu et al., 2021). The expression of circPDE4D and linear PDE4D mRNA was found not to be correlated indicating that distinct mechanisms produce these transcript types. Wu et al. identified regulatory regions in the flanking introns (i.e. upstream of exon 2 and downstream of exon 5) that are crucial for circPDE4D circularization. Through specific CRISPR-Cas9 editing, the authors were able to decrease circPDE4D expression and determine that QKI response elements (QRE) are involved in circularization of the PDE4D pre-mRNA (Wu et al., 2021). QREs bind the RNA-binding protein quaking (QKI), which has previously been shown to regulate the circularization of many pre-mRNAs (Conn et al., 2015). The functional role of circPDE4D remains largely to be determined, but Wu et al. identified that circPDE4D can bind specific microRNAs and thereby indirectly modulates the translation of mRNA that otherwise would be degraded by, the now scavenged, microRNA. In the same study, circPDE4D was found to be downregulated in osteoarthritic cartilage tissue and intra-articular injection of circPDE4D could mitigate impairments in a mouse model of osteoarthritis (Wu et al., 2021).

As circPDE4D contains four exons that are also present in linear long-form PDE4D mRNA, it can be speculated that circPDE4D scavenges miRNAs that bind linear long form PDE4D mRNA and circPDE4D may therefore indirectly modulate PDE4D protein expression. Moreover, circRNAs can also directly regulate protein

function, protein scaffolding and protein localization, but these potential roles still remain to be determined for circPDE4D (Kristensen et al., 2019). These recent findings underline the complex transcriptional control of the *PDE4D* gene and warrant further investigation into non-protein-coding transcripts of the PDE4 gene family.

For murine *Pde4d*, the additional long PDE4D11 and supershort PDE4D10 isoforms have been described (Chandrasekaran et al., 2008; Lynex et al., 2008)(**Supplementary Table 1**). Furthermore, additional murine PDE4D transcripts have been identified that all encode supershort PDE4D2, but which are generated through diverse exon incorporation resulting in diverse 5'UTR sequences and lengths (Chandrasekaran et al., 2008)(**Supplementary Table 1**). Regarding 5'UTR and 3'UTR lengths, discrepancies exist regarding the reported transcript lengths when comparing NCBI Gene and Ensembl databases. 5'UTR lengths can differ depending on where the transcriptional machinery binds the DNA and initiates transcription, as exemplified for mouse PDE4D1 (McLaughlin et al., 1993). Similarly, the PDE4 transcript's 3'UTR may differ in length as it contains multiple polyadenylation sites (Sullivan et al., 1998; Wang et al., 2003). According to this variability at the 5'UTR and 3'UTR, certain gene databanks may show other lengths for the first unique and last common exons compared to those displayed in **Figure 1**. As 5'UTR and 3'UTR sequences have been found to function as 'zip-codes' for specific intracellular transcript transport, it can be speculated that variation in these PDE4 transcript sequences may contribute to specific intracellular localization patterns for the different PDE4 isoforms (Andreassi and Riccio, 2009; Chin and Lecuyer, 2017). Wang et al. identified 10 putative consensus polyadenylation signals in the 3'UTR of PDE4D mRNA, which indicates that multiple transcripts that differ in their 3'UTR length can be generated depending on which polyadenylation site is utilized (Wang et al., 2003). Subsequently, differences in 3'UTR length may give rise to mRNA transcripts that exhibit different recognition motifs for several RNA-binding proteins (Di Liegro et al., 2014). For example, self-complementary sequences in mRNA can form secondary

structure hairpin loops that can be recognized and bound by RNA-binding proteins to regulate mRNA stability and transportation (Di Liegro et al., 2014). Depending on PDE4 3'UTR length, different secondary structures may be formed and bound by different transport proteins, which localize the transcript to distinct intracellular compartments. There, the specific PDE4 mRNA may be locally translated after which the PDE4 protein isoform can be anchored to other proteins or membranes through its (isoform-specific) amino acids (see section **PDE4 modifications and interactions**). Although the role of 5'UTR and 3'UTR sequence differences in mRNA transportation has not yet been explicitly demonstrated for PDE4 transcripts, these sequence differences could provide another mechanism through which PDE4 subtypes and isoforms can display a distinct cell- and tissue-type specific intracellular distribution.

The intracellular localization of PDE4 isoforms is particularly regulated via isoform-specific N-termini at the protein level, encoded by typical unique exon incorporation. These different N-termini permit PDE4 isoforms to interact with protein partners or membranes in specific intracellular compartments (Houslay et al., 1995). In *Aplysia*, apPDE4 was found to require N-terminus residues for membrane binding, which indicates a conserved role for isoform-specific N-termini in PDE4 localization (Jang et al., 2010). Likewise, different mammalian PDE4 subtypes (e.g. PDE4B and PDE4D) locate to different intracellular compartments (Blackman et al., 2011).

In addition to the scaffolding function, interactions with partner proteins can, as mentioned above, act upon the enzyme's conformational state and hence affect its catalytic activity and inhibitor affinity. Similarly, PDE4 subtypes and isoforms are subject to post-translational modifications that differentially alter the conformation and activity of the enzyme.

To develop more efficacious and safer PDE4 inhibitors for different diseases, it is crucial to identify which PDE4 subtypes and isoforms should be targeted in

disease-relevant tissues and cell types. Similarly, insight into which PDE4 subtypes and isoforms mediate adverse effects will determine which specific targets to avoid to improve the treatment's safety profile. Additionally, understanding the conformational state of the isoform(s) involved in the compartmentalized signaling important to treat the disease at hand determines which compounds would be most potent. In the following section, an overview is provided on the different manners by which PDE4 activity and inhibitor affinity is influenced by post-translational modifications and interactions with partner proteins.

## II. PDE4 MODIFICATIONS AND INTERACTIONS

As mentioned before, catalytically active PDE4 isoforms can be categorized as long, short, or supershort based on the presence of UCR1 and UCR2 domains. Depending on the PDE4 subtype, isoform category, and unique N-terminal features, different post-translational modifiers and interaction partners can influence the conformation of the enzyme. These mechanisms allow for the dynamic regulation of the amount, localization, and activity of PDE4 enzymes in order to shape and respond to spatiotemporal cAMP signaling (as also recently reviewed for all PDE gene families: (Baillie et al., 2019)). The seminal work by Houslay and collaborators has provided a detailed understanding of which PDE4 amino acid residues are crucial for several modifications and interactions (Klussmann, 2016). Those post-translational modifications and protein-protein interactions for which involved PDE4 domains or specific amino acid residues have been identified are graphically represented in **Figure 2**. These and other modifications and interactions, for which involved regions have not been determined, are discussed below in more detail. Furthermore, the known functional consequences of several modifications and interactions on PDE4 activity and inhibitor binding are elaborated upon in the following subsections and are summarized in **Table 1**.

### A. UCR1-UCR2 module, dimerization, and phosphorylation

PDE4 activity is profoundly regulated by its own UCR domains as, in long isoforms, the C-terminal of UCR1 forms a module with the N-terminal of UCR2, which auto-inhibits its activity through the capping of the UCR2 alpha-helix NQVSE[F/Y]ISXTFLD across the catalytic domain (Beard et al., 2000; Houslay and Adams, 2010; Kovala et al., 1997; Lim et al., 1999) (see also **Figure 3, Table 1 and Supplementary Video**). Furthermore, the UCR1 and UCR2 domains enable long isoforms to homo- and heterodimerize, while short and supershort isoforms (lacking UCR1) exist as monomers (Xie et al., 2014). The UCR1-UCR2 module is disrupted

upon serine phosphorylation in the conserved protein kinase A (PKA) consensus motif RRES in UCR1 of all long PDE4 isoforms. The liberation of this UCR1-UCR2 module attenuates the auto-inhibitory effect causing enzyme activation (Beard et al., 2000; Hoffmann et al., 1998). As PKA is a direct downstream effector protein of cAMP, this modification serves as a negative feedback loop restoring cAMP levels through enhanced PDE4 activity. Although PKA phosphorylation can activate all long isoforms, the amplitude of PKA activation can differ among these isoforms as reported for long PDE4D isoforms (Richter et al., 2005). This indicates that additional regulatory mechanisms influence enzymatic activity. For example, the presence of additional PKA phosphorylation sites in PDE4D3 and PDE4D7, upon combined PKA phosphorylation, leads to differential effects in terms of catalytic activity (Byrne et al., 2015; Collins et al., 2008; Sette and Conti, 1996). Indeed, unique phosphorylation in the N-terminal PDE4D7, but not at the unique site in PDE4D3, induces an inhibitory effect on activity as opposed to PKA phosphorylation at the conserved UCR1 site (Byrne et al., 2015). Although PKA phosphorylation provides a negative feedback loop to restore cAMP levels, this regulation can be influenced by other protein interactors as well. For example, when PDE4D is bound by the protein CC2D1, phosphorylation by PKA is prevented (Al-Tawashi and Gehring, 2013; Al-Tawashi et al., 2012). In addition to PKA, it was found that the same serine residue in UCR1 can be phosphorylated by Akt (Fang et al., 2015). Other conserved serine residues in the UCR1 also serve as phosphorylation sites for other kinases such as MK2, SIK1, CDK5, and AMPK, which may modulate PDE4 activity by similarly affecting UCR1-UCR2 module formation/stabilization (Bolger, 2016; Houslay et al., 2019; Kim et al., 2015; MacKenzie et al., 2011; Plattner et al., 2015; Sheppard et al., 2014). Next to phosphorylation events, binding of phosphatidic acid or phosphatidylserine to the UCR1-UCR2 module increases PDE4 activity (Nemoz et al., 1997). The regulatory role of the UCR1-UCR2 module is further supported by the observation that several PDE4D mutations associated with the rare genetic disorder acrodysostosis localize

to these regions, causing either increased or decreased PDE4D activity (Briet et al., 2017; Gurney et al., 2015; Kaname et al., 2014).

**Figure 2. Graphical representation of regulatory protein domains of PDE4 proteins and PDE4 amino acids or domains involved in inherent features of PDE4 enzymes, post-translational modifications and interactions with protein partners.**

Colored rectangles indicate regulatory domains. Inherent features of PDE4 enzymes and associated amino acids are also visualized in [Supplementary Video](#). Those post-translational modifications and protein-protein interactions for which the involved PDE4 domains or specific amino acid residues have been identified are listed in this figure. If specific amino acids in involved regions have been identified to mediate the modification or interaction, these amino acids are indicated in bold and underlined. In case the specific amino acids are unidentified, the involved region is indicated by the region's first and last amino acids connected by a line. Of note, for simplicity, PDE4D amino acids are shown for non-conserved amino acids involved in modifications or interactions that can occur in multiple PDE4 subtypes. Importantly, not all proteins or mechanisms in **Figure 2** are listed in **Table 1**, and vice versa as one of both aspects (i.e. either involved amino acids or effect of activity) may not have been revealed yet. More detailed information on each of the modification or interaction can be found in the main text and the references as listed below. *Abbreviations and references: N-term, N-terminus; LR1, linker region 1; UCR1/2, upstream conserved region 1/2; LR2, linker region 2; C-term, C-terminus; UCR1-UCR2 interaction (Beard et al., 2000); dimerization (Bolger et al., 2015; Cedervall et al., 2015; Lee et al., 2002; Richter and Conti, 2002; 2004; Xie et al., 2014); Mg<sup>2+</sup> binding (Alvarez et al., 1995; Laliberte et al., 2000; Liu et al., 2001; Saldou et al., 1998); PKA, protein kinase A (Alvarez et al., 1995; Beard et al., 2000; Bolger, 2016; Byrne et al., 2015; Hoffmann et al., 1998; Mackenzie et al., 2002; Sette and Conti, 1996); Akt (Fang et al., 2015); MK2, MAPK-activated protein kinase 2 (Bolger, 2016; Houslay et al., 2017; Houslay et al., 2019; Mackenzie et al., 2011); SK1, salt-inducible kinase 1 (Kim et al., 2015); CDK5, cyclin-dependent kinase 5 (Plattner et al., 2015); AMPK, AMP-activated protein kinase (Sheppard et al., 2014); CaMKII, calcium/calmodulin-dependent kinase II (Mika et al., 2015); oxidative stress kinase (Bolger, 2016; Hill et al., 2006); ubiquitination (Li et al., 2009); ERK, extracellular signal-regulated kinase (Baillie et al., 1999; Mackenzie et al., 2000); JNK, c-Jun N-terminal kinase (Bogoyevitch and Kobe, 2006; Sharrocks et al., 2000; Zeke et al., 2015); SUMOylation (Li et al., 2010); caspase-3 (Huston et al., 2000);  $\beta$ -arrestin (Baillie et al., 2007; Bolger, 2016; Bolger et al., 2006; Smith et al., 2007); RACK1, receptor of activated protein C kinase 1 (Bird et al., 2010; Bolger et al., 2006; Bolger et al., 2002; Smith et al., 2007; Yanwood et al., 1999); DISC1, disrupted in schizophrenia 1 (Cheung et al., 2007; Millar et al., 2005; Murodoch et al., 2007; Soda et al., 2013); myomegalin (Verde et al., 2001); Shank2, SH3 and multiple ankyrin repeat domains protein 2 (Lee et al., 2007); LIS1 (Murodoch et al., 2011); B55 $\alpha$  PP2a subunit (Yun et al., 2019b); all spectrin (Creighton et al., 2008); Src/Lyn/Fyn (Beard et al., 1999; O'Connell et al., 1996); mAkap (Carlisie Michel et al., 2004; Dodge et al., 2001); AKAP9 (Terrenoire et al., 2009); AKAP185 (Stefan et al., 2007); Rheb (Kim et al., 2010); Meng et al., 2017); HSP20 (Sin et al., 2011); PHD2 (Huo et al., 2012); integrin  $\alpha 5$  (Yun et al., 2016; Yun et al., 2019b); Mdm2 (Li et al., 2009); calcineurin (Zhu et al., 2010); p75<sup>NTR</sup> (Houslay et al., 2019; Sachs et al., 2007); membrane binding (Baillie et al., 2002); XAP/AIP (Bolger et al., 2003); Lyn (Beard et al., 2002); Lyn + Src (McPhee et al., 1999); p62 (SQSTM1) (Christian et al., 2010).*

## **B. Phosphorylation at sites other than UCR1**

Through the use of multiple phosphorylation sites, PDE4 functionality can be modulated in a conditional manner requiring multi-phosphorylation as has been reported for the role of PDE4D9 in mitosis (Sheppard et al., 2014). Next to the UCR1, the N-terminal of the catalytic domain comprises phosphorylation sites for CaMKII and an 'oxidative stress' or 'switch' kinase. CaMKII phosphorylation is PDE4D-specific and induces enzyme activation in a manner distinct from PKA activation (Mika et al., 2015). In response to oxidative stress, an as of yet unidentified 'oxidative stress' or 'switch' kinase can increase PDE4 enzyme activity by switching the inhibitory effect of phosphorylation by extracellular signal-regulated kinase (ERK) to an activating effect (Bolger, 2016; Hill et al., 2006). Similarly, inhibition of PDE4D by ERK is diminished upon PIASy-mediated SUMOylation, while this SUMOylation augments PKA activation of PDE4A and PDE4D (**Figure 2 and Table 1**) (Li et al., 2010).

Phosphorylation by ERK is established through the docking of ERK at the 'KIM' and 'FQF' motifs that are located in catalytic domains and C-terminus, respectively (**Figure 2**) (Houslay and Baillie, 2003). Upon docking of ERK the consensus motif PXSP can be phosphorylated, which is present at the end of the catalytic domain in PDE4B, -4C and -4D. Although PDE4A phosphorylation at this motif has been detected, this is unlikely induced by ERK, given the absence of the consensus motif, or it does not result in changed PDE4A activity (Baillie et al., 2000; Lario et al., 2001). Phosphorylation by ERK reduces the catalytic activity of long and supershort PDE4B, -4C and -4D isoforms; presumably by intramolecular stabilization of the UCR2-capped configuration (Baillie et al., 2000; Houslay and Baillie, 2003). Conversely, short isoforms are activated upon ERK phosphorylation. However, removal of the UCR2 region in the short PDE4B2 form prevents an effect by phosphorylation by ERK, which supports the notion that UCR2-capping is required for ERK-mediated effects (Rocque et al., 1997b). Moreover, when ERK phosphorylation is paired with additional PKA or 'switch' kinase phosphorylation, enzyme activity will increase in long isoforms as well (Hill et al., 2006; Hoffmann et

al., 1999). Apart from these direct effects on PDE4 activity, phosphorylation by ERK may make PDE4 less prone to proteolysis (Lenhard et al., 1996). The PDE4D5 isoform may be minimally subjected to phosphorylation by ERK as its unique N-terminus binds the protein phosphatase B55 $\alpha$  subunit, which dephosphorylates at the ERK site reversing its inhibition (Yun et al., 2019a). Furthermore, PDE4D5 specifically interacts with the proteins  $\beta$ -arrestin and RACK1, which can block the docking and phosphorylation by ERK, respectively (**Table 1**) (Bolger et al., 2006). Consequently, PDE4 activity can be increased upon these interactions, as reported for RACK1 (Bird et al., 2010; Bolger et al., 2006; Bolger et al., 2002; Yarwood et al., 1999). Of note, binding of  $\beta$ -arrestin and RACK1 ablates dimerization, but they bind mutually exclusively due to overlapping binding residues in the PDE4D5 N-terminus (Bolger, 2016). Additional Mdm2-mediated ubiquitination primes PDE4D5 to interact with  $\beta$ -arrestin rather than RACK1 (Li et al., 2009). Although  $\beta$ -arrestin preferentially binds PDE4D5, when bound to the RXFP1 receptor, it prioritizes binding PDE4D3 (Halls and Cooper, 2010). These findings indicate that, due to differential and combined interactions with partner partners, phosphorylation and binding events may be stimulated, prevented, or countered in an isoform-specific manner.

The ERK-associated KIM docking motif can also be utilized by c-Jun N-terminal kinase (JNK) (Houslay and Adams, 2003; Sharrocks et al., 2000). Intriguingly, the specific isoforms PDE4A8, PDE4B1, and PDE4D7 all contain an additional, evolutionary conserved, docking site for JNK in their unique N-terminal (**Figure 2**). Previously, it has been demonstrated that PDE4B1 can indeed bind JNK, but it remains to be verified whether JNK effectively phosphorylates PDE4 and whether this changes PDE4 enzymatic activity (Zeke et al., 2015). A putative JNK phosphorylation site can be found in the accessible LLSTPAL motif in the catalytic domain, which corresponds with the heptapeptidic consensus sequence surrounding the JNK phosphorylation site (Bogoyevitch and Kobe, 2006).

**Table 1.** Overview of modifications and interactions that influence PDE4 activity and the affinity of PDE4 inhibitors

Effect on PDE4 activity	Interaction/modification	Effect on inhibitor affinity	Comments	References
Increase	Akt	-		(Fang et al., 2015)
	B55α PP2a subunit	-	dephosphorylation at ERK site on PDE4D5	(Yun et al., 2019a)
	Calcineurin	-	protects against degradation	(Zhu et al., 2010)
	CaMKII	-		(Mika et al., 2015)
	Caspase-3 cleavage	-		(Huston et al., 2000)
	CDK5	-	possible synergistic activation by PKA	(Plattner et al., 2015)
	ERK	-	short isoforms of PDE4B, -4C and -4D only	(Baillie et al., 2000; MacKenzie et al., 2000)
	mAKAP/AKAP6	-	presumably through mAKAP-sequestered PKA	(Carlisle Michel et al., 2004; Dodge et al., 2001)
	Metal binding (Mg <sup>2+</sup> )	increase (R-rolipram, S-rolipram, CDP-840, cilomilast, roflumilast, piclamilast, PMNPQ)		(Huang et al., 2007; Laliberte et al., 2000; Liu et al., 2001; Saldou et al., 1998)
	Oxidative stress 'switch' kinase	no effect (rolipram)	switches ERK inhibition to activation, phosphomimetic mutation prevents dimerization	(Bolger, 2016; Hill et al., 2006)
	Phosphatidic acid	-	dimerization necessary for activation	(Grange et al., 2000; Nemoz et al., 1997; Richter and Conti, 2004)
	Phosphatidylserine	-		(Nemoz et al., 1997)
	PI3Kγ	-		(D'Andrea et al., 2015; Ghigo et al., 2012)
	PKA	increase (rolipram, BPN14770, RS-25344, RS-33793)		(Alvarez et al., 1995; Bolger, 2016; Hoffmann et al., 1998; MacKenzie et al., 2002; Sette and Conti, 1996; Zhang et al., 2018)
	RACK1	increase (rolipram)	ablates dimerization	(Bird et al., 2010; Bolger et al., 2006; Bolger et al., 2002; Yarwood et al., 1999)
Rheb	-	stabilizes PDE4D protein expression	(Kim et al., 2010; Meng et al., 2017)	

	SIK1	-		(Kim et al., 2015; Liu et al., 2020)
<b>Decrease</b>	CC2D1A	-	prevents activation by PKA	(Al-Tawashi and Gehring, 2013)
	DISC1	-	PKA phosphorylation releases DISC1	(Cheung et al., 2007; Millar et al., 2005; Murdoch et al., 2007)
	ERK	-	long and supershort isoforms of PDE4B, -4C and -4D only	(Baillie et al., 2000; MacKenzie et al., 2000)
	PHD2	-	presumably induces PDE4 protein degradation	(Huo et al., 2012)
	PKA (PDE4D7 only))	-		(Byrne et al., 2015)
	Smurf2	-	ubiquitination and degradation of PDE4B	(Cai et al., 2018)
	SUMO E3 ligase PIASy	-	augments PKA phosphorylation, reduces ERK inhibition	(Li et al., 2010)
	UCR1-UCR2 interaction	no effect (IBMX, rolipram, piclamilast, RS-25344)		(Beard et al., 2000; Saldou et al., 1998)
	XAP2/AIP	increase (rolipram)		(Bolger et al., 2003)
<b>None</b>	dimerization	increase (R-rolipram), no effect (piclamilast) / no effect (rolipram) / increased (rolipram)	dimerization enables UCR2 to bind rolipram	(Bolger et al., 2015; Cedervall et al., 2015; Richter and Conti, 2004)
	Lyn, Src	increase for rolipram		(Beard et al., 2002; Beard et al., 1999; McPhee et al., 1999; O'Connell et al., 1996)
	MK2 phosphorylation	-	phosphomimetic mutation prevents dimerization; attenuation PKA activation and interaction with DISC1 and AIP; enhances interaction of PDE4A4 with p75NTR	(Bolger, 2016; Houslay et al., 2019; MacKenzie et al., 2011)
	p75NTR	-		(Houslay et al., 2019; Sachs et al., 2007)
	PKA (PDE4D3-only)	-	upon phosphorylation PDE4D3 is released from Nde1	(Collins et al., 2008; Sette and Conti, 1996)
<b>Not reported</b>	$\beta$ -arrestin2	-	ablates dimerization and preferentially binds monomeric PDE4D5	(Baillie et al., 2007; Bolger, 2016; Bolger et al., 2006)

**Figure 3. Tertiary structure of dimerized PDE4B demonstrating capping of UCR2 across the catalytic domain and helices 10-11.** Crystal structure was derived from Protein Data Bank (PDB: 4WZI, (Cedervall et al., 2015)). UCR1 and UCR2 regions of both monomers are indicated in purple and red, respectively. Catalytic domains are colored cyan and have the catalytic metals (i.e. Mg<sup>2+</sup> and Zn<sup>2+</sup>) embedded as shown by the spheres. Wheat-colored helices form part of the linking region between catalytic domains and, non-modelled, C-termini. A three-dimensional representation of the image is provided in [Supplementary Video](#).

### **C. Indirect regulation of PDE4 activity and interactions**

Next to the aforementioned mechanisms, cellular PDE4 activity can be regulated through mechanisms distinct from phosphorylation. These regulatory

mechanisms may be therapeutically relevant for the disease of interest, as exemplified by the disrupted in schizophrenia 1 (DISC1) protein. DISC1 is a PDE4 interaction partner and has been found to be a risk factor for the development of psychiatric diseases when mutated (Cheung et al., 2007; Millar et al., 2005; Soda et al., 2013). DISC1 can bind and inhibit both PDE4B and PDE4D through homologous amino acids causing occlusion of the catalytic domain, while additional subtype-specific binding sites allow for a stronger interaction with PDE4B than with PDE4D (**Figure 2**) (Murdoch et al., 2007). Consequently, upon cAMP elevation, DISC1 dissociates from PDE4D while retaining its interaction with PDE4B resulting in functionally distinct roles for these PDE4 subtypes (Murdoch et al., 2007). Hence, mutations in either DISC1 or PDE4, or both, can impair or enhance this inhibitory action of DISC1 leading to aberrant PDE4 activity.

Through regulation of PDE4 mRNA and protein stability, cellular PDE4 activity can also be influenced. For example, cold-inducible RNA-binding protein (CIRP), which acts as a cellular stress regulator can stabilize PDE4B and PDE4D mRNA expression (Xie et al., 2020). Moreover, PDE4B mRNA was found to be stabilized by the common RNA modification  $N^6$ -methyladenosine, providing another mechanism to regulate PDE4 translation and subsequent activity (Huang et al., 2020). At the protein level, PDE4 expression and activity were found to be decreased upon overexpression of the oxygen-sensing protein PHD2 through hydroxylation of a specific site in the catalytic domain (**Figure 2**) (Huo et al., 2012). PDE4D contains a phosphodegron motif in its C-terminus, which upon dual phosphorylation by casein kinase I (CK1) and glycogen synthase kinase  $3\beta$  (GSK3 $\beta$ ) induces PDE4D degradation (**Figure 2**). However, through binding of the serine/threonine protein phosphatase calcineurin, PDE4D can be protected against phosphodegron-mediated degradation, which would stabilize PDE4 activity (Zhu et al., 2010). Noteworthy, both calcineurin inhibitors and PDE4 inhibitors are used in the treatment of atopic dermatitis (Papier and Strowd, 2018). Based on the calcineurin-PDE4 interaction, these calcineurin

inhibitors may, at least in part, be effective through stimulation of PDE4 degradation. Likewise, the small GTPase Rheb stabilizes PDE4D protein expression and dissociates upon cAMP elevation to activate the mTOR pathway (Kim et al., 2010; Meng et al., 2017). Lastly, PDE4B ubiquitination can be induced upon interaction with the E3 ubiquitin ligase Smurf2 (Cai et al., 2018). Thus, PDE4 activity is indirectly regulated through control of its degradation. Conversely, when these regulatory mechanisms are affected in a disease state (e.g. in case of DISC1 mutations), PDE4 activity can consequently become dysregulated.

#### **D. Conformational states impacting upon PDE4 activity and inhibitor binding**

Upon modifications and interactions, PDE4 can exist in different conformational states. Historically, this has been recognized by PDE4 activity that could be distinguished based on different binding affinities for rolipram; a high-affinity rolipram binding site (HARBS) and low-affinity rolipram binding site (LARBS), see also **section PDE4 inhibitors** below (Jacobitz et al., 1996; Rocque et al., 1997a; Rocque et al., 1997b; Souness and Rao, 1997). Multiple studies have demonstrated several factors that contribute to the existence of distinct conformers. For example, binding  $Mg^{2+}$  in the catalytic domain dose-dependently increases enzymatic activity but also increases the affinity to bind rolipram and other inhibitors (**Table 1**) (Alvarez et al., 1995; Laliberte et al., 2000; Wilson et al., 1994). Similarly, phosphorylation by PKA and RACK1 binding both increase PDE4 activity and induce an increase in rolipram affinity (MacKenzie et al., 2002; Zhang et al., 2018). However, the effect of phosphorylation by PKA on rolipram affinity can be different per long isoform (MacKenzie et al., 2002). Interestingly, increases in enzyme activity upon phosphorylation by PKA may actually be a consequence of an increase in  $Mg^{2+}$  sensitivity, which subsequently would facilitate cAMP catalysis as well as binding of certain inhibitors through water-mediated interactions (Laliberte et al., 2000; Saldou et al., 1998). Indeed, as proposed by Houslay and Adams, modifications at the N-terminus may be relayed via conformational changes to the catalytic domain to

eventually influence enzyme activity (Houslay and Adams, 2003). For example, upon PKA phosphorylation and possibly also other PDE4-activating phosphorylation events in the UCR1 (**Figure 2**), the UCR1-UCR2 module and/or UCR2-catalytic domain interactions may be disrupted (Beard et al., 2000; Houslay and Adams, 2003). Subsequently, this altered conformation could change the orientation of helices 10 and 11 in the catalytic domain that flank the catalytic metals, thereby impacting the way these metals are held in place. More specifically, helices 10 and 11 form a tweezer-like structure (**Figure 4**, dark blue helices) and are connected by a loop (**Figure 4**, orange) which may interact with UCR2 and/or LR2 residues (**Figure 4**). As such, N-terminal modifications and interactions can, directly or through modulation of this UCR2/LR2 stretch, alter the conformation of this connecting loop, thereby changing the way helices 10 and 11 stabilize catalytic metal binding. Consequently, catalytic activity and metal-mediated inhibitor binding will be influenced. Vice versa, inhibitor binding can impact the ability of PDE4 forms to engage in protein-protein interactions via 'inside-out signaling', which supports the notion that conformational changes are relayed between the catalytic domain and N-terminal regions. (Day et al., 2011; Terry et al., 2003). Interestingly, as the LR2 region is not conserved among PDE4 subtypes, its effect on metal coordination through interaction with the helix 10-11 connecting loop may be different per PDE4 subtype. Indeed, deletion of the UCR2 and LR2 regions significantly decreases the sensitivity of PDE4D, but not PDE4A or PDE4B, to bind  $Mg^{2+}$  (Saldou et al., 1998).

PDE4 enzymes exhibiting increased activity are not analogous to increased inhibitor affinity, as also interactions that do not increase PDE4 activity influence inhibitor binding. Binding of the proteins XAP2 and Lyn enhances the sensitivity to rolipram, but has a negative or no effect on PDE4 activity, respectively (**Table 1**)(Bolger et al., 2003; McPhee et al., 1999). Furthermore, it has been postulated that the HARBS conformer constitutes of long isoforms since their dimerized state stabilizes HARBS (Richter and Conti, 2004). However, HARBS is not dependent on

dimerization or the presence of UCR1 but rather is formed by inhibitor-UCR2 interactions indicating that (super)short isoforms can also exhibit HARBS (Jacobitz et al., 1996). Indeed, truncated proteins similar to supershort forms that do possess the inhibitory UCR2 helix exhibit both HARBS and LARBS, whilst further deletion of the entire UCR2 only displays LARBS (Rocque et al., 1997a; Rocque et al., 1997b). These findings correspond to the fact that UCR2/LR2 residues may bind the connecting loop between helices 10-11 to regulate catalytic metal ion coordination. Absence of these residues would ablate the ability to change metal coordination and the consequent change in enzyme activity and metal-engaging inhibitor binding. Thus, both HARBS and LARBS comprise different states that depend on dimerization, degree of metal binding, interaction with partner proteins, and phosphorylation but which display similar affinities to inhibitors. Selective inhibition of PDE4 forms in HARBS or LARBS conformation has been shown to yield distinct biological effects although the exact PDE4 isoforms and/or conformation-mediators remain to be specified. For example, inhibition of HARBS in the brain was found to produce antidepressant-like effects in rats (Zhang et al., 2006). Moreover, using PDE4 inhibitors that selectively bind HARBS or LARBS, Boomkamp et al. identified that inhibition of HARBS, but not LARBS, mediates myelination and neurite outgrowth *in vitro* (Boomkamp et al., 2014).

The notion that inhibitors can display divergent affinities towards isoforms in different conformational states and that conformation-specific inhibition can exert different biological effects has implications for drug discovery and development. Hence, it is crucial to understand which isoforms, in what conformational state, should be targeted in the disease of interest that determine the most potent inhibitor (see also **section PDE4 inhibitors**).

**Figure 4. Tertiary structure of dimerized PDE4B demonstrating helices 10-11 and its connecting loop.** One monomer is colored dark gray while helices 10-11, flanking the catalytic metals, of the other monomer are now colored dark blue. The connecting loop between helices 10-11 is indicated in orange. The C-terminal of UCR2 (red loose end in the middle) is connected to the N-terminus of the catalytic domain (loose end in cyan in right-bottom corner) via LR2 which is not modeled, but which would fold across the helix 10-11 connecting loop. Modifications and interactions in the N-terminal are hypothesized to be relayed, via UCR2/LR2-associated changes, to the connecting loop of helices 10-11 to change catalytic metal ion coordination which subsequently impacts cAMP catalysis and affinity towards certain metal-interacting inhibitors.

## **E. Intracellular PDE4 localization and anchoring**

### **1. A-kinase anchoring proteins (AKAPs)**

In addition to activity-altering interactions, PDE4 engages in protein-protein interactions that contribute to specific intracellular localization patterns. Accurate localization of PDE4 enzymes is crucial for the directed breakdown of compartmentalized cAMP. Many studies have indicated an essential role for A-kinase anchoring proteins (AKAP) in tethering signaling molecules regulating cAMP signaling, including PDE4 subtypes and isoforms (reviewed in e.g. (McConnachie et al., 2006; Omar and Scott, 2020; Wild and Dell'Acqua, 2018)). Through specific binding domains, the extensive collection of AKAPs allows the assembly of signaling modules consisting of PKA and PDE4 that are anchored to specific organelles, receptors (e.g. to the 5HT4b receptor (Weninger et al., 2014)), or cytoskeletal proteins (McConnachie et al., 2006)). Important to note is that phosphorylation of the PDE4D3-specific PKA site facilitates its binding to mAKAP, which localizes to the ryanodine receptor (RyR) (Carlisle Michel et al., 2004; Lehnart et al., 2005). Additionally, as PKA is bound to AKAPs as well, tethering PDE4D3 to mAKAP also promotes phosphorylation of the common PKA site causing PDE4 activation near the RyR (Dodge et al., 2001). Moreover, PDE4D3 can be brought into contact with I<sub>K</sub> channels through selectively binding AKAP9 (Terrenoire et al., 2009; Terrin et al., 2012). Interestingly, the PDE4 residues involved in binding AKAP18 $\delta$  are present in all isoforms, but tissue-specific expression causes only PDE4D3 and PDE4D9 to be associated with AKAP18 $\delta$  (aka AKAP7) in the kidney, highlighting the importance of studying cellular, tissue- or disease-relevant PDE4 expression (Stefan et al., 2007). Furthermore, PDE4 has shown to associate with AKAP450 (aka AKAP350, CG-NAP, Hyperion or Yotiao) (McCahill et al., 2005; Tasken et al., 2001), AKAP95 (AKAP8) (Asirvatham et al., 2004; Clister et al., 2019), AKAP3 (does not bind PDE4D) (Bajpai et al., 2006), MTG16B (Asirvatham et al., 2004), AKAP149 (Asirvatham et al., 2004), AKAP5 (also known as AKAP79) (Choi et al., 2011; Kocer et al., 2012), and Gravin (also

called AKAP12, AKAP250 or SSeCKS; which binds PDE4D3 and PDE4D5) (Willoughby et al., 2006). Although direct effects of AKAP binding on PDE4 activity remain largely undetermined, it is known that myomegalin (PDE4DIP) utilizes the same PDE4 residues that mediate UCR1-UCR2 interaction and dimerization, and hence could influence the conformational state and activity of the bound PDE4 (Uys et al., 2011; Verde et al., 2001). Moreover, interactions between specific PDE4 forms and specific AKAPs may only occur in specific cell types or organs as more specifically described elsewhere ((Baillie et al., 2019; Zaccolo et al., 2021)).

## 2. Not AKAP-related

Independently of AKAPs, certain PDE4 isoforms can bind to specific structures through subtype- or isoform-specific amino acids. For example, the PDE4D4 and PDE4A4 isoforms have been found to localize to specific organelles and the plasma membrane through interactions with SH3 domains of the tyrosine kinases Lyn, Src, and Fyn via their N-terminus proline residues that possibly affect inhibitor binding (**Table 1**) (Beard et al., 2002; Beard et al., 1999; Huston et al., 2000; McPhee et al., 1999; O'Connell et al., 1996). Additionally, PDE4D4 is anchored to the cytoskeleton via interaction with  $\alpha$ II spectrin (Creighton et al., 2008). The PDE4D-specific LR2 sequence allows interaction with integrin  $\alpha$ 5, which brings PDE4D in vicinity to a phosphatase that rectifies ERK-induced phosphorylation (**Figure 2**) (Yun et al., 2016; Yun et al., 2019a). The supershort PDE4A1 is membrane-bound via specific residues in its N-terminus (Baillie et al., 2002; Shakur et al., 1993), and similar observations have been made for the short PDE4B2 isoform (Lobban et al., 1994). Likewise, PDE4A4 is associated with the membrane, but upon cleavage by caspase-3, it is redistributed within the membrane (Huston et al., 2000). Hence, post-translational modifications can alter intracellular distribution and compartmentalization, which is also supported by the fact that phosphorylation events can translocate membrane-associated PDE4 to the cytosol (Liu and Maurice,

1999). Through interactions in UCR1 and UCR2, mainly long PDE4D forms have been found to interact with Shank2 (Lee et al., 2007). As Shank2 also binds cystic fibrosis transmembrane conductance regulator (CFTR), this may explain the association of PDE4 enzymes with CFTR (Blanchard et al., 2014; Lee et al., 2007). Lastly, PDE4 enzymes can be intracellularly recruited to the p75<sup>NTR</sup> and neuropilin receptors, which are involved in neuronal growth (Ge et al., 2015; Houslay et al., 2019; Sachs et al., 2007). Vice versa, PDE4 enzymes can modulate cellular signaling cascades through scaffolding other molecules away from their usual binding partners. This is exemplified by the fact that PDE4 can recruit LIS1 causing it to disassociate from dynein. Subsequently, dynein function will be impaired causing changes in microtubule transport and directed cell migration (Murdoch et al., 2011). As many interactions between PDE4 and partner proteins rely on isoform-specific amino acid stretches, these interactions can localize PDE4 isoforms to distinct subcellular compartments. Consequently, different PDE4 isoforms may regulate spatially distinct cAMP signaling cascades and isoform-specific PDE4 inhibition would enable more precise modulation of these different cAMP cascades.

### III. PDE4 INHIBITORS

As an important cellular regulator of cAMP levels and associated intracellular signal transduction, PDE4 has been investigated as therapeutic target in a wide variety of disorders. Based on promising observations upon treatment with non-selective PDE inhibitors and the prototypical PDE4-selective inhibitor rolipram, PDE4 inhibitors have been developed with improved potency. Despite increased potency, clinical progression of PDE4 inhibitors has been hampered primarily due to the occurrence of severe adverse side effects (see also below in section **PDE4 side effects**). Therefore, to improve treatment efficacy and safety, PDE4 inhibitor specificity next to potency may have to be considered. As discussed above, both the diversity in PDE4 isoforms that display distinct enzymatic properties, the amino acid differences among subtypes as well as isoform-specific N-termini allow for complex activity regulation by post-translational modifications and interactions with partner proteins. Eventually, this regulatory control can influence the enzyme's activity through conformational changes. These specific interactions, non-conserved amino acids and distinct conformational states can provide the opportunity to target PDE4 activity more specifically at the subtype and isoform level.

This section will outline several aspects that should be considered when determining PDE4 inhibitor specificity towards subtypes or isoforms by providing an extensive overview of inhibitor screening literature. Furthermore, this section will summarize which PDE4 inhibitors have been developed to show more specific targeting of subtypes, isoform and/or conformations.

#### A. PDE4 inhibitors and HARBS and LARBS

As mentioned above, HARBS and LARBS represent different conformational states that exhibit different inhibitor affinities and that can be influenced through several mechanisms (e.g. metal binding, phosphorylation or binding of partner proteins). Based on the observation that preferential inhibition of HARBS was

correlated with adverse effects, efforts were made to develop PDE4 inhibitors with reduced HARBS binding (Barnette et al., 1995; Duplantier et al., 1996). Selective inhibition of HARBS or LARBS can produce distinct cellular effects, which provides additional support for improved therapeutic potential of conformation-specific inhibitors (Boomkamp et al., 2014; Zhang et al., 2006). However, HARBS and LARBS conformations can occur in all PDE4 subtypes and HARBS seems to require a part of the UCR2 domain, suggesting that both long and short PDE4 isoforms can exert HARBS (Souness and Rao, 1997). Thus, although HARBS and LARBS can be preferentially bound by certain inhibitors, selective binding of these conformations does not directly allow for PDE4 subtype or isoform selectivity. However, as described in **subsection II.D.**, HARBS and LARBS conformations may, in part, be a consequence of differences in the orientation of two helices that flank the catalytic domain and that coordinate the catalytic metals (Houslay and Adams, 2003). The positioning of these helices is likely impacted by LR2 residues, which are non-conserved among PDE4 subtypes. Associated with these PDE4 subtype-specific LR2 residues, changes in metal orientation between HARBS and LARBS may be different among the PDE4 subtypes, which is supported by subtype-specific sensitivities to  $Mg^{2+}$  depending on whether LR2 is present or not (Saldou et al., 1998). Hence, although highly speculative, it may be possible to alter PDE4 activity subtype-selectively by means of allosteric modulation in the LR2 region which subsequently modifies enzyme activity through changes in metal orientation. In support of this hypothesis, the kinases CaMKII and the 'oxidative stress kinase' both phosphorylate residues in the LR2 region and have been shown to modulate PDE4 activity (**Figure 2** and **Table 1**) (Hill et al., 2006; Mika et al., 2015).

As PDE4 subtypes and isoforms regulate distinct cellular and behavioral functions, PDE4 subtype-selective inhibition, rather than preferential binding of HARBS or LARBS, may show superior treatment efficacy compared to non-selective PDE4 inhibition (Blackman et al., 2011; Zhang et al., 2017).

## **B. Determining PDE4 inhibitor subtype- and isoform-selectivity in assays**

### 1. The influence of PDE4 construct and assay type on PDE4 inhibitor screenings

Given the importance of subtype-, isoform- or conformation-specific inhibition for treatment efficacy and safety, it is crucial to assess these properties of PDE4 inhibitors. Initial high-throughput screenings often utilized the catalytic domain of a single PDE4 subtype only to determine the ability of a compound to inhibit PDE4 activity. Since these catalytic domain constructs may not express UCR2 domains, these enzymes do not resemble cellular PDE4 activity as UCR2-mediated auto-inhibition or capping is not possible. Furthermore, the lack of the UCR2 alters the  $Mg^{2+}$  sensitivity of the enzyme and could therefore skew screening results as both enzyme activity and  $Mg^{2+}$ -mediated inhibitor binding may be impacted (Saldou et al., 1998). Hence, compound screening for PDE4 inhibitory activity using the catalytic domain of a single PDE4 subtype only will provide limited insight into the compound's potential subtype-selectivity. Subtype-selectivity should therefore be assessed by using constructs of these different PDE4 subtypes and constituting a full-length protein rather than the catalytic domain only. Linked to this, as catalytic domains show large similarity among PDE4 subtypes, selectivity can more likely be achieved through interactions with amino acid residues outside of the catalytic domain (Wang et al., 2007a). Thus, to determine potential subtype-selectivity of PDE4 inhibitors, the use of full-length PDE4 constructs will provide a better understanding compared to using only PDE4 catalytic domains.

PDE4 inhibitors can be tested in both cellular assays and assays utilizing purified PDE4, but affinity values cannot be directly compared across studies as they are dependent on the used assay. For example, affinity values derived from assays using purified PDE4 versus overexpressed PDE4 constructs in a cellular assay can show an 80-fold difference (Wunder et al., 2013). Moreover, other studies showed that inhibitor affinity to isolated PDE4 enzymes does not reflect its potency in intact tissue

(Harris et al., 1989). Furthermore, differences exist regarding which cell lines and heterologous expression systems are used for cellular assays or purified protein assays, respectively, which prevents comparison across studies that using different methodologies. Although assays using purified protein can provide a detailed understanding on the affinity and potency of an inhibitor, these assays do not reflect dynamic changes in (subtype-specific) PDE4 conformational states and associated affinity changes that would occur in a cellular environment. Hence, when assessing potential subtype-specificity of PDE4 inhibitors, affinity values can only be compared within studies and the most accurate approximation of *in vivo* PDE4 inhibition can be assessed by using full-length enzymes that contain all regulatory elements.

**Table 2** provides a comprehensive overview of studies in which affinities of PDE4 inhibitors towards different PDE4 subtypes were assessed. As mentioned, affinity values, indicated as nanomolar concentrations that cause half-maximum inhibition (IC<sub>50</sub>), cannot be compared across studies as different assays may have been used. For each subtype construct, it is indicated whether a particular isoform was used and whether the construct entailed the full-length protein or was truncated. From this overview, it becomes evident that several studies have assessed compound selectivity for PDE4 subtypes by using constructs of different isoform categories (i.e. long, short, or supershort) per subtype. Several studies indicate that inhibitors can exhibit different affinities towards PDE4 subtypes. For example, cilomilast seems to show slightly higher affinity towards PDE4D, irrespective of whether truncated supershort or long isoforms are used (Asaka et al., 2010; Huang et al., 2007). Interestingly, many compounds show notable lower affinity towards PDE4C, whilst other compounds (e.g. UFM24) preferentially bind PDE4C (Tsai et al., 2017b). As PDE4C shows the least homology with the other subtypes, PDE4C-specific residues therefore may either promote or impede inhibitor binding, yielding PDE4C-specific or PDE4C-averse binding, respectively.

**Table 2. PDE4 inhibitors tested for their selectivity against different PDE4 subtypes**

Importantly, seemingly subtype-selectivity may be a result of or biased by preferred binding to an isoform of particular length rather than specificity to the PDE4 subtype. Since isoforms of different lengths exhibit different properties due to the presence or absence of regulatory domains (e.g. long forms can dimerize via UCR1-UCR2 interactions), isoform categories of the same PDE4 subtype may be preferentially bound by certain inhibitors. To reveal potential isoform-specific binding, **Table 3** presents an overview of compounds that were tested, in the same assay, for their affinity towards PDE4 constructs of different lengths of the same PDE4 subtype. Various compounds show increased affinity towards the long isoforms compared to its catalytic domain only, in which the regulatory UCR1, UCR2, and C-terminus domains are deleted (e.g. (Wunder et al., 2013)). As these regulatory domains convey effects of post-translational modifications and interactions with partner proteins, these modifications and interactions themselves may exert an effect on inhibitor affinity within the same PDE4 isoform as explained earlier. Indeed, for example, PKA phosphorylation has been shown to profoundly impact inhibitor affinity (e.g. (Hoffmann et al., 1998)) which supports the notion that assays using purified, non-phosphorylated enzyme cannot be compared to cellular assays in which PDE4 activity is dynamically regulated (Wunder et al., 2013). As certain modifications or interactions can only occur in specific PDE4 subtypes or isoforms to induce conformational changes (**Figure 2**), these conformations provide actually other means of achieving more specific PDE4 inhibition. Therefore, it is crucial to understand how different conformational states, caused by modifications or interactions, impact inhibitor affinity.

Several studies have investigated these effects of conformational state on PDE4 inhibitor affinity and these findings are summarized in **Table 4**. By means of mutations that mimic phosphorylation by PKA and ablate phosphorylation by ERK, the effects of PKA phosphorylation *per se* on inhibitor affinity can be simulated (Burgin et al., 2010; Hoffmann et al., 1998). This phosphorylation-mimicking mutation profoundly increases the affinity of rolipram and BPN14770 to bind the long form PDE4D7 (Zhang et al., 2018) (see **Table 4**), indicating that inhibitors can preferentially bind PKA-phosphorylated PDE4 states. Mechanistically, increased inhibitor affinity upon phosphorylation by PKA could be due to a more favorable positioning of UCR2, increased Mg<sup>2+</sup> sensitivity to aid inhibitor binding, or a combination of both. Interestingly, although PDE4 phosphorylation by PKA also increases enzymatic activity as a biological feedback loop, this feedback mechanism would actually facilitate or strengthen binding of these inhibitors. Since PKA-phosphorylated PDE4 displays higher enzymatic activity, preferential inhibition of this activated state may actually produce more potent effects on cAMP levels in an *in vitro* or *in vivo* setting. Conversely, as inhibitors may bind only the phosphorylated fraction of PDE4 forms, inhibition of non-phosphorylated PDE4 may be minimal, yielding only a partial

inhibition of total PDE4 activity. Therefore, it is essential to consider the potency of PDE4 inhibitors in addition to their affinity when determining which inhibitor, with its affinity profile against different PDE4 subtypes, isoforms and conformations, shows most therapeutic benefit in the disease of interest.

In addition to specific PDE4 phosphorylation, PDE4 isoforms can show different affinities towards inhibitors depending on whether these isoforms are located in the cytosol or have complexed with other cellular structures, as elaborately investigated by Houslay and collaborators (Bolger et al., 1997; Huston et al., 1997; Huston et al., 1996; Rena et al., 2001; Wallace et al., 2005). By subcellular fractionation, both cytosolic and particulate fractions of PDE4 forms can be separated, which can show differential affinities to inhibitors in an isoform-dependent manner (**Table 4**). Per cellular fraction, PDE4 isoforms may engage in different protein-protein interactions, which subsequently can alter their conformation leading to divergent effects on inhibitor affinity. Thus, based on its specific subcellular localization and local interactions or modifications, the same PDE4 isoform can adopt different conformations which may be preferentially bound by certain inhibitors (e.g. the different affinities of rolipram towards particulate and cytosolic PDE4A4 **Table 4**). As such, these inhibitors can modulate PDE4 activity with different potency at the subcellular level.

**Table 4. PDE4 inhibitors tested for their selectivity against different PDE4 conformational states or PDE4 isoforms in different cellular fractions.**

## 2. Optimizing PDE4 inhibitor screenings

The involvement of PDE4 in various cellular processes makes these enzymes attractive pharmacological targets, but simultaneously makes non-specific PDE4 inhibition prone to modulating unwanted biological mechanisms. Hence, to optimize the efficacy and safety of PDE4 inhibitors, it is crucial to specify which PDE4 subtypes or isoforms are involved in the (disease-affected) cellular functions that are to be modified. In this subsection, we highlight how the choice of assay, target specification, and the use of 'toolbox' compounds that apply distinct binding mechanisms can guide drug development towards safe and efficacious PDE4 subtype/isoform inhibition.

Firstly, considering that PDE4 enzymes can dynamically adopt several conformational states that can show different affinities to inhibitors, screening assays using purified PDE4 constructs are limited in predicting the inhibitory potential of a compound as they assess affinities against a static, rather than a dynamic, enzyme. Hence, cell-based screening assays will more accurately indicate the PDE4 inhibitory potential of compounds when other influencing factors including phosphorylation events, interactor proteins and biological feedback mechanisms are present. When using cell-based assays, we argue it is essential to assess a PDE4-regulated phenotypical or physiological read-out that is relevant to a healthy or pathological

process of interest rather than an overall change in cAMP levels. Thus, the quality (i.e. cAMP elevation at the desired intracellular location) of PDE4 inhibition is more important than the quantity (i.e. profound cAMP elevation but not intracellularly confined) to achieve efficacious treatment while minimizing side effects. The use of cell-based assays that focus on a phenotypical or physiological read-out may also lead to discovery of efficacious PDE4 inhibitors with additional activity on other relevant targets, which would be undetectable in assays using solely purified PDE4 enzymes.

Using a cell-based, possibly disease relevant, assay, experiments can be conducted to specify which PDE4 subtypes and isoforms regulate the chosen phenotypical or physiological read-out. By means of genetic knockout (e.g. using CRISPR-Cas9) or shRNA-mediated knockdown, it can be specified which PDE4 subtypes or individual PDE4 isoforms regulate the biological read-out process. Conveniently, the typical PDE4 gene structures allow for targeting of isoforms selectively as they each contain (parts of) a unique exon that can be targeted at the DNA level (e.g. using CRISPR-Cas9) or the transcript level (e.g. using shRNAs) (**Figure 1**). Validation of the role of specific subtypes or isoforms in the chosen read-out can be performed by overexpressing the subtype/isoform in order to assess whether it induces an opposite effect on the read-out compared to subtype/isoform knockout. The involvement of specific isoforms in the process of interest can also be corroborated using a dominant-negative approach in which a catalytically inactive PDE4 form is being overexpressed. Subsequently, overexpressed inactive PDE4 isoforms will (partly) displace endogenous, active PDE4 isoforms inducing local decreases in PDE4 activity. Functional roles of specific PDE4 isoforms have already been successfully identified using this approach (e.g. (Bolger et al., 2020; Campbell et al., 2017; Perry et al., 2002)). While dominant-negative PDE4 forms can isoform-specifically displace endogenous forms, their overexpression may also cause excessive scaffolding of PDE4 interaction proteins that could alter cellular signaling.

Hence, depending of the biological mechanism of interest, validation of the role of specific PDE4 subtypes and isoforms may be best supported by a combination of the abovementioned strategies. Upon target specification and validation, drug design is suggested to be conducted in a structure-based manner. In case the functionally relevant PDE4 forms belong to a specific subtype, subtype-specific differences in PDE4 structure may be exploited to develop PDE4 subtype-selective inhibitors as described in the subsection 'Mechanisms for PDE4 subtype selectivity: interactions with regulatory domains'.

Since there already exist PDE4 inhibitors that preferentially bind certain subtypes, isoforms and/or conformations (**Tables 2-4**), these compounds can be used as 'toolbox' compounds to determine which binding mechanism induces the most prominent effect on the assay read-out. Parallel insights from the target validation approaches and use of 'toolbox' compounds would eventually provide the insight and understanding to develop PDE4 inhibitors that apply a particular binding mode to selectively bind and inhibit the most relevant PDE4 forms to subsequently efficaciously attenuate a biological dysfunction of interest.

### **C. Mechanisms for PDE4 subtype selectivity: interactions with regulatory domains**

#### **1. Interactions with the UCR2**

Although the different subtypes possess highly similar catalytic domains, subtle amino acid differences exist in regulatory regions (i.e. UCR2 and C-terminus) that can be positioned across the catalytic pocket. When the UCR2 is capped, certain residues can interact with inhibitors as their side chains extent into the catalytic domain (**Figure 3** and [Supplementary Video](#)). UCR2 capping is postulated to occur via intermolecular actions in long, dimerized PDE4 isoforms where the UCR2 of one monomer folds across the catalytic domain of the other monomer (Cedervall et al., 2015). As the UCR2 also is auto-inhibitory in monomeric, short PDE4D1, intramolecular UCR2-capping may also occur (Kovalala et al., 1997). Irrespective of

whether UCR2 capping occurs in *trans* (intermolecularly) or in *cis* (intramolecularly), inhibitors can engage in interactions with UCR2 residues. Intriguingly, in primates, a polymorphism has occurred in PDE4D leading to the expression of a phenylalanine instead of tyrosine in the UCR2 region. This subtype-specific difference has been successfully exploited, and validated by mutation studies, to generate PDE4D-selective inhibitors (e.g. BPN14770) that interact with the PDE4D-specific phenylalanine in the UCR2 region (**Table 4**) (Burgin et al., 2010). Interestingly, Gurney et al. have shown that certain compounds that utilize UCR2 for binding, like BPN14770, behave as partial inhibitors (Gurney et al., 2019). It is hypothesized that, in dimerized PDE4, through inhibitor-UCR2 interactions at one monomer the other UCR2 cannot effectively *trans*-cap the other monomer. Since this UCR2-capping is involved in compound binding, inhibitor binding at this monomer will be reduced, resulting in overall partial inhibition. Conversely to binding the UCR2 phenylalanine, inhibitors can preferentially interact with the tyrosine residue in PDE4A-C, producing PDE4D-sparing actions, as reported for ABI-4 (PF-06266047) (Hedde et al., 2017). Notably, several classes of PDE4 inhibitors have found to stabilize a UCR2-capped state as elaborately indicated by Day and colleagues (Day et al., 2011). While PDE4 modifications and protein-protein interactions can influence inhibitor affinity by influencing UCR2-capping, stabilization of UCR2-capping by certain inhibitors can, conversely, also alter the conformation of regulatory domains that affect PDE4 modifications and interactions (Terry et al., 2003). In the case of PDE4A4, stabilization of UCR2 capping by inhibitor binding causes its intracellular redistribution, demonstrating that inhibitor binding can induce additional cellular changes next to elevation of local cAMP levels (Day et al., 2011). This use of UCR2 by certain compounds makes their affinity also dependent on post-translational modifications and interactions with partner proteins as they can influence the UCR2 capping state as explained before.

## 2. Interactions with the C-terminus

Similar to the use of UCR2 residues to achieve subtype selectivity, amino acid differences in the C-terminus can be employed to achieve subtype-specific inhibitor binding. Through interactions with residues unique to the PDE4B C-terminus, PDE4B-selectivity has been achieved for the compounds A33 and a tetrahydrobenzothiophene inhibitor (see **Table 4**) (Fox et al., 2014; Kranz et al., 2009; Naganuma et al., 2009). The C-terminus is capped across the catalytic domain in an intramolecular manner as the linker region between C-terminus and the catalytic domain is too short to achieve capping the other monomer in a PDE4 dimer. Inhibitors that employ C-terminus residues may therefore preferentially bind capped over uncapped states producing a degree of conformation-dependent binding. As both UCR2 and C-terminus capping are dependent on multiple cellular events including phosphorylation or interactions with partner proteins, conformation-dependent inhibitors may bind PDE4 in a selective spatial and/or temporal manner.

### **D. Stereoisomerism and metabolites of PDE4 inhibitors**

In 1983, it had already been described that the enantiomer (R)-rolipram and racemic rolipram are more potent in increasing cerebral cAMP levels than (S)-rolipram (Schneider, 1984; Wachtel, 1983a; b). Accordingly, several studies have indicated that (R)-rolipram shows higher PDE4 affinity than (S)-rolipram (Barnette et al., 1996; Laliberte et al., 2000; Torphy et al., 1992). This suggests that stereoisomerism of PDE4 inhibitors can influence the inhibitor's affinity depending on whether a racemic mixture or purified enantiomer is tested. Both (R)-rolipram and (S)-rolipram seem to exhibit similar binding modes in PDE4D2 crystal structures, but increased affinity of (R)-rolipram may be conveyed via other isoforms and/or conformational states than those captured by the reported crystal structures (Huai et al., 2003). Indeed, rolipram can adopt a slightly different conformation in crystals that include UCR2 domains (Cedervall et al., 2015). For another set of enantiomeric

inhibitors (L-869298 and L-869299), stereochemistry does change the binding mode in a  $Mg^{2+}$ -interacting manner which is concurrent with differences in affinity (Huai et al., 2006). Next to the aforementioned enantiomeric inhibitors, also for the PDE4D-selective inhibitor GEBR32a, different affinities are reported for its enantiomers (**Table 3**) (Cavalloro et al., 2020). Hence, in case of racemic inhibitors, it has to be considered that enantiomers can exhibit different binding modes and affinities for specific PDE4 conformations. Consequently, certain enantiomers may display favorable pharmacological properties superior to its racemic mixture. Enantiomer-specific effects can provide important insights into the molecular binding modes crucial for efficacy and can subsequently facilitate pharmacophore determination and inhibitor optimization.

Similar to the use of racemic PDE4 inhibitor mixtures, metabolism of administered PDE4 inhibitors can produce multiple metabolites that each show differences in their binding mode and affinity. For example, the PDE4 inhibitor roflumilast is metabolized into roflumilast N-oxide which shows distinct subtype-selectivity compared to roflumilast itself (**Tables 2 and 3**) (Claveau et al., 2004; Huang et al., 2007; Wunder et al., 2013). The inhibitory potential of inhibitor metabolites on PDE4 activity should therefore be taken into account as combined actions of PDE4 inhibitors and its metabolites may cause certain PDE4 subtypes, isoforms or conformations to be more potently inhibited *in vivo*, resulting in a more favorable or unfavorable pharmacological profile.

### **E. Modulators of PDE4 activity**

Next to PDE4 inhibitors, molecules have been described that influence PDE4 activity in a non-inhibiting manner. For example, atropine, a muscarinic acetylcholine receptor antagonist, has been described to allosterically inhibit PDE4 while also potentiating rolipram binding (Perera et al., 2017). These effects correspond to those of modulation by several intracellular factors as discussed above in the **section PDE4 modifications and interactions**. In contrast to allosterically inhibiting molecules,

PDE4 activity can also be stimulated through allosteric binding. For example, early studies by the Conti and coworkers showed that binding of antibodies targeting the UCR2 auto-inhibitory domain increased PDE4 activity similar to phosphorylation by PKA (Conti et al., 1995; Lim et al., 1999).

More recently, also small molecules have been described that increase PDE4 activity through allosteric binding (Omar et al., 2019). More specifically, these compounds bind and activate long, dimerized PDE4 and thereby mimic the activating actions of PKA. This mechanistic similarity of activation is further supported by the inability of these small molecules to increase activity in PKA-mimicking PDE4 mutants. Hence, these small molecule allosteric activators have therapeutic utility in disorders in which cAMP signaling is aberrantly increased. For example, in autosomal dominant polycystic kidney disease (ADPKD), elevated cAMP levels promote the formation of cysts. Omar et al. have demonstrated that the use of allosteric activators can successfully diminish cyst formation in cell models of ADPKD. It can be speculated that allosteric PDE4 activators also have therapeutic applicability in other disorders displaying elevated cAMP signaling, such as the genetic condition McCune–Albright syndrome in which gain-of-function Gs alpha subunit mutations lead to exaggerated cAMP synthesis (Innamorati et al., 2018; Levine, 1999). Hence, PDE4 enzymes have therapeutic utility as pharmacological targets both in conditions displaying reduced and heightened levels of cAMP.

Lastly, PDE4 peptide fragments have been developed which can either stimulate PDE4 activity (Wang et al., 2015), or reduce activation by ‘scavenging’ the PDE4-activating phosphorylation by Cdk5 (Plattner et al., 2015).

## **IV. ADVERSE EFFECTS OF PDE4 INHIBITION**

Although PDE4 inhibition shows therapeutic potential in a variety of disease areas, clinical exploitation of PDE4 inhibitors has often been held back by dose limitations caused by adverse side effects. Side effects upon PDE4 inhibitor administration are mainly gastro-intestinal in nature (i.e. nausea, vomiting and diarrhea), but also headaches and dizziness have been reported (e.g. (Compton et al., 2001)). These side effects may be overcome by more precise targeting of PDE4 subtypes, isoforms or conformational states. Accordingly, subtype-selective PDE4 inhibitors have been developed which exploit subtle sequence differences and distinct conformational states that may result from different PDE4 lengths and specific interactions and modifications (e.g. (Burgin et al., 2010; Fox et al., 2014; Hedde et al., 2017)). While this allows for more precise targeting, insight into which PDE4 subtypes or isoforms mediate unwanted effects is therefore crucial to understand which subtypes/conformations not to target. This section will discuss PDE4 expression and functionality in brain and bodily areas, and potential molecular mechanisms related to the different PDE4-mediated side effects. In addition, an overview is provided of those PDE4 inhibitors that have been tested for possible adverse side effects.

### **A. Hypothermia**

Several preclinical studies using mice, rats and guinea pigs have demonstrated that PDE4 inhibitors can induce hypothermia (McDonough et al., 2020b; Wachtel, 1983a; b; c). These effects seem to be regulated via PDE4-mediated dopamine signaling in the hypothalamus which is supported by the fact that PDE4 inhibitors that difficultly enter the brain have less profound effects on body temperature (McDonough et al., 2020b). Whilst not explicitly described as adverse side effect in humans, hypothermia may contribute to uncomfortable feelings during treatment with PDE4 inhibitors.

## **B. Dizziness**

PDE4 inhibition has also been reported to cause dizziness (Blokland et al., 2019). In cochlear and vestibular nuclei in the brainstem, PDE4D was found to be highest expressed compared to other PDE4 subtypes (Iwahashi et al., 1996; Perez-Torres et al., 2000). More specifically, PDE4D1, PDE4D2, and PDE4D3 mRNA was expressed in the rat dorsal cochlear and vestibular nuclei (Miro et al., 2002b). As the cochlear and vestibular nuclei relay signaling from the inner ear, altered cAMP modulation by PDE4 inhibition in these areas may provoke feelings of dizziness and, through subsequent signaling to other brain stem areas, promote nausea and emesis. Interestingly, in the vestibular apparatus in the inner ear itself, PDE4D is expressed and rolipram induces endolymphatic hydrops in the mouse, which is associated with feelings of dizziness (Degerman et al., 2017; Nakashima et al., 2016).

## **C. Gastro-intestinal**

### **1. Diarrhea**

Concerning effects of PDE4 inhibition on the gastro-intestinal system, diarrhea has been reported as an adverse effect. Through PKA-dependent activation of the cystic fibrosis transmembrane conductance regulator (CFTR), PDE4 inhibition may cause diarrhea by elevating intestinal  $\text{Cl}^-$  secretion (Chao et al., 1994). Specifically, PDE4D may mediate this effect upon PDE4 inhibition as PDE4D has been found to be recruited to CFTR via binding the scaffolding protein Shank2 (Lee et al., 2007). Moreover, PDE4 inhibition can facilitate 5HT<sub>4</sub> receptor-mediated acetylcholine release causing contraction of large intestinal circular smooth muscle (Pauwelyn et al., 2018). Specifically, the PDE4D3 and PDE4D5 isoforms have been found to associate with 5HT<sub>4</sub>(b) receptors and may, therefore, be involved in gastrointestinal effects caused by PDE4(D) inhibition (Weninger et al., 2014). Despite the fact that diarrhea has been reported as a PDE4-mediated adverse event, it is striking that roflumilast has actually been found to exhibit antidiarrheal effects in mice which may

be associated with antispasmodic actions of roflumilast in the jejunum (Rehman et al., 2020).

## 2. Nausea and emesis

Regarding nausea and emesis, PDE4 actions within both the central nervous and gastro-intestinal system seem to be involved. In an early study, intravenous administration of rolipram and Ro20-1724 were found to increase gastric acid and pepsin secretion in anesthetized rats (Puurunen et al., 1978). Correspondingly, Lamontagne et al. suggested that, in the stomach, pepsinogen-releasing chief cells primarily express the PDE4D subtype while acid-releasing parietal cells expressed PDE4A (Lamontagne et al., 2001). Moreover, binding of specifically HARBS configurations in gastric glands showed strong correlation with the degree of gastric acid secretion (Barnette et al., 1995). Interestingly, gastric transit was found to be more strongly inhibited by roflumilast than by a selective PDE4B inhibitor, which may suggest PDE4B inhibition contributes relatively little to gastric side effects (Suzuki et al., 2013). Recently, it was shown that non-selective PDE4 inhibition induces gastroparesis (i.e. delayed gastric transit) in mice (McDonough et al., 2020a). More importantly, this study showed that genetic ablation of any of the four PDE4 subtypes does not affect gastroparesis or protect against inhibitor-induced gastroparesis, which suggests that two or more PDE4 subtypes contribute to PDE4-mediated gastroparesis. As gastroparesis is strongly associated with nausea and emesis in humans, this physiological effect of PDE4 inhibition warrants further investigation as a possible predictive measure for the side effect profile of PDE4 inhibitors (Grover et al., 2019).

Although PDE4 inhibition causes profound local gastric effects, emesis is eventually effectuated through signaling in brainstem nuclei such as the nodose ganglion, area postrema (AP), and nucleus tractus solitarius (NTS) (du Sert et al., 2012; Miller and Leslie, 1994). In the nodose ganglion of the squirrel monkey, cell bodies

of gastric vagal nerve fibers can be found in which predominantly PDE4D is present compared to lower expression levels of PDE4C or long PDE4A forms (Lamontagne et al., 2001). Similarly, the AP and NTS were found to mainly express PDE4D and to a smaller extent PDE4B, in the mouse (Cherry and Davis, 1999), rat (Iwahashi et al., 1996; Perez-Torres et al., 2000; Takahashi et al., 1999) and human brain (Mori et al., 2010). PDE4D expression was also found in medulla oblongata neurons that are innervated by substance P, which has been reported to be involved in emetic responses upon PDE4 inhibition (Lamontagne et al., 2001; Robichaud et al., 1999). At the PDE4D transcript variant level, mRNA of PDE4D1 and PDE4D4 showed high expression in the rat AP compared to lower levels of PDE4D2 and PDE4D5, and absence of PDE4D3. Furthermore, low levels of PDE4D2, PDE4D4 and PDE4D5 were detected in the NTS (Miro et al., 2002b). Strikingly, in another study by Miró and colleagues, no PDE4D4 mRNA was detected in the rat AP (Miro et al., 2002a). Human data regarding PDE4D mRNA content in the AP also suggests that PDE4D4 is not abundantly present, while the highest expression was found for PDE4D3 and PDE4D9 (VANMIERLO, 2019).

In addition to localization studies showing high expression of PDE4D in emesis-related brainstem areas, mechanistically, PDE4D also seems to mediate emetic responses. In a study by Robichaud et al., PDE4D, but not PDE4B, knockout mice displayed reduced sleeping time under xylazine/ketamine-induced anesthesia, a measure of emetic-like behavior. Furthermore, the PDE4 inhibitor PMNPQ did reduce anesthesia duration in wild-type and PDE4B-deficient mice but not in PDE4D-deficient mice which again indicates an involvement of PDE4D in emetic-like behavior (Robichaud et al., 2002b). Xylazine/ketamine-induced anesthesia assesses emetic-like behavior in non-vomiting species through  $\alpha_2$ -adenergetic receptor antagonism (Nelissen et al., 2019; Robichaud et al., 2002a; Robichaud et al., 2001). The involvement of PDE4D in this mechanism corresponds with the expression of both  $\alpha_2$  adrenoceptor and PDE4D mRNA in the NTS (Lamontagne et al., 2001;

Scheinin et al., 1994). However, also PDE4A and PDE4B seem to mediate  $\alpha$ 2-dependent signaling, at least in retinal rod bipolar cells (Dong et al., 2014). PDE4 inhibitors may enhance neuronal firing in both the AP and NTS of rats as higher expression of the neuronal activity marker Fos was observed in these regions upon administration of rolipram or PMNPQ in rats (Bureau et al., 2006). Accordingly, AP neurons could be excited by cAMP, which would be elevated upon inhibitor administration (Carpenter et al., 1988). Noteworthy, AP neurons exhibit a hyperpolarization-activated cation current ( $I_h$ ) that acts as pacemaker current and which is found to be activated through stimulation of cAMP signaling (Funahashi et al., 2003). Consequently, PDE4 inhibition may increase the frequency of this pacemaker current leading to an increased firing rate. Actually, the influence of PDE4 on pacemaker currents has already been demonstrated in the sinoatrial node of the heart (St Clair et al., 2017). The xylazine/ketamine-induced anesthesia test suggests that PDE4 inhibition alters AP activity through antagonizing  $\alpha$ 2-adrenergic receptor signaling (Nelissen et al., 2019). Accordingly,  $\alpha$ 2-adrenergic receptor stimulation was shown to inhibit cAMP and close hyperpolarized cyclic nucleotide-gated (HCN) channels (Wang et al., 2007b). Vice versa, PDE4 inhibition could enhance cAMP, open HCN channels, increase  $I_h$  currents and increase the firing rate of AP neurons leading to an emetic response. Anesthesia induced by injecting an  $\alpha$ 2 adrenergic agonist into the locus coeruleus, which innervates the AP, of rats could be reversed by rolipram. However, pretreatment of a PKA inhibitor blocked the effects of rolipram, suggesting emetogenic effects by PDE4 inhibitors are mediated through actions requiring cAMP-PKA signaling (Correa-Sales et al., 1992). Moreover, phosphorylation of PKA and ERK, downstream kinases of cAMP, was found to be highest during peak emesis in AP neurons (Zhong and Darmani, 2017).

These findings support the notion that PDE4-mediated cAMP signaling and its downstream effectors contribute to emetic behavior. Still, the exact mechanism underlying these adverse side effects caused by PDE4 inhibitors remains to be

resolved. Since the AP may in part be outside of the blood-brain barrier, emetic effects can be dependent on both peripheral and central actions (Miller and Leslie, 1994). Based on the gene deletion and localization studies discussed above, PDE4D seems to be involved in central and peripheral actions leading to the induction of emesis. However, emetic(-like) effects cannot be attributed entirely to PDE4D as the PDE4D-selective inhibitors GEBR32a, V11294A and BPN14770 appear to be well-tolerated in animals and/or healthy volunteers [NCT02648672][NCT02840279] (Gale et al., 2003; Gale et al., 2002; Ricciarelli et al., 2017; Rogers and Giembycz, 1998; Sutcliffe et al., 2014). It is likely that multiple PDE4 subtypes and isoforms in different bodily tissues contribute collectively to PDE4-associated side effects, as also suggested by Richter and colleagues (McDonough et al., 2020a). Hence, subtype- or isoform-selective PDE4 inhibitor may yield less severe side effects. As PDE4 subtypes and isoforms have non-redundant roles and show specific intracellular localization, certain subtypes or isoforms may be specifically involved in mechanisms that eventually evoke unwanted effects. The potency of the inhibitor to inhibit these particular isoforms would then explain their potency to induce adverse effects. However, which exact PDE4 subtypes and isoforms mediate these processes remains to be determined. Another explanation may lay in the differential affinities of the compound to different PDE4 conformational states. Indeed, correlations have been found between the degree of binding HARBS and emetic effects (Christensen et al., 1998; Duplantier et al., 1996; Hirose et al., 2007). Inhibitors that preferentially target LARBS or show no preference would therefore be safer, which is supported by the relatively low emetogenicity of cilomilast and roflumilast (Davis et al., 2009). In contrast, the PDE4D-selective inhibitor BPN14770 preferentially binds HARBS but appears to be well-tolerated in humans [NCT02648672][NCT02840279](Tetra, 2016). Although BPN14770 can bind HARBS, its relatively low emetogenicity may be explained by its PDE4D-selective inhibition and/or the fact that it acts as a partial inhibitor (see **section PDE4 inhibitors** (Burgin et al., 2010)). Thus, the occurrence of

adverse effects may not fully attributed to preferential binding of HARBS or LARBS, or to PDE4D-selective inhibition, but rather is more complex involving inhibition of specific PDE4 subtypes and/or isoforms in different central and peripheral tissues.

Thus, it has been shown that it is possible to develop PDE4 inhibitors with safer pharmacological profile compared to the prototypical rolipram. In **Table 5**, an overview is provided of several compounds that have been tested for their ability to elicit PDE4-associated side effects compared to rolipram. Because of discrepancies among studies regarding the type of test, species and administration routes used, results can mainly be compared within studies using the same procedures. **Table 5** indicates that multiple PDE4 inhibitors induce emetic and emetic-like effects at doses more than 30-fold of those induced by rolipram (e.g. CT-2450 and D159687), whilst some compounds require lower doses than rolipram (e.g. PMNPQ and D157140). Since adverse side effects are often assessed in non-primate species (e.g. mice, rats, dogs and ferrets), it should be considered that these tests do not accurately reflect the potential emetic effects of PDE4 inhibitors that exploit the primate PDE4D-specific phenylalanine in the UCR2 region. In addition, rodents cannot vomit and therefore require an indirect emesis test like the xylazine/ketamine test or pica feeding test. Despite the fact that several compounds can be used safely at higher doses than rolipram, their therapeutic potential is also dependent on the doses required for the desired therapeutic effect. As such, the eventual therapeutic windows of these compounds, i.e. the range of doses that elicit therapeutic, yet no adverse, effects may still be similar to those of rolipram for a specific disease indication. Nevertheless, a wide variety of PDE4 inhibitors has been developed with improved affinities to specific subtypes and/or conformational states (**Tables 2-4**) and minimized emetogenicity compared to rolipram (**Table 5**). Thus, to establish safer and more efficacious PDE4 inhibition for a disease, it should be determined which PDE4 subtypes, isoforms, or conformations have to be targeted to determine which inhibitor displays the broadest therapeutic window.

#### **D. Strategies to minimize PDE4-mediated adverse side effects**

Although PDE4 inhibition can produce several adverse side effects as described above, multiple strategies can be exploited to minimize or prevent these unwanted responses while retaining efficacy. Most notably, more selective inhibition of PDE4 forms may be pursued to improve treatment efficacy and/or avoid inhibiting PDE4 forms mediating adverse side effects. Regardless, a mechanistic understanding of which PDE4 subtypes, isoforms and/or conformational states mediate adverse effects will aid in the development of new-generation PDE4 inhibitors that then should actually avoid potently inhibiting these forms. Several PDE4 inhibitors already exist that preferentially bind non-conserved amino acids and different conformational states (see **Table 4**). Moreover, partial inhibitors may provide a safer pharmacological profile compared to full inhibitors through distinct potencies for different PDE4 conformations and/or subtypes (Gurney et al., 2011). In case PDE4 inhibition is desired in peripheral organs rather than the central nervous system, PDE4 inhibitors with limited brain penetrance may minimize the occurrence of side effects that are mediated through central actions (Aoki et al., 2001a). Likewise, depending on the target organ, a particular route of administration can be chosen to minimize systemic exposure (e.g. intranasal or topical administration, or via inhalation) (Tralau-Stewart et al., 2011). More precise targeting of PDE4 inhibitors has also been achieved by using inhibitor-antibody conjugates, which are internalized specifically by cells that express the antibody's antigen (Yu et al., 2016). Systemic exposure can also be minimized by using PDE4 inhibitors that are quickly degraded, as recently reported (Larsen et al., 2020).

Finally, combination treatments may reduce the severity of PDE4-mediated side effects. For example, it has been described that diarrhea caused by high doses of roflumilast can be attenuated when paired with a cyclooxygenase inhibitor (Peter et al., 2011). Furthermore, inhibition of different PDE families (e.g. PDE4 and PDE5 or PDE2 and PDE4) can produce synergistic effects which enables to use lower doses, with reduced chances of adverse effects, to produce the same treatment effect

(Bollen et al., 2015; Gulisano et al., 2018; Paes et al., 2020b). Lastly, the treatment of certain diseases, in which cAMP elevation is desired, may benefit from dual PDE4/PDE7 inhibitors which may subsequently reduce PDE4-selective inhibition and its associated side effects (Rucilova et al., 2020; Sharma et al., 2019).

**Table 5. PDE4 inhibitors tested for their potential to induce emesis-like behavior (rodents) or emesis compared to rolipram**

Compound	Emetic(-like) dose (µg/kg)	Emetic(-like) dose ratio to rolipram	Adm. route	Species	Test	Study

## V. OUTLOOK

As important regulators of cAMP signaling in the entire body, the PDE4 enzyme family presents an interesting and promising pharmacological target in a broad range of disease areas. Accordingly, PDE4 inhibition has preclinically shown therapeutic potential for many diseases, yet its non-selective inhibition is associated with severe adverse effects which has seriously hampered its translation to the clinic. To increase efficacy and avoid adverse effects more selective targeting is required. This is actually possible as PDE4 enzymes consists of multiple similar, but different, subtypes that each comprise different isoforms. In this review it is summarized how these subtypes and isoforms can, through PDE4-inherent regulation, post-translational modifications, and interactions with other proteins, adopt different conformational states to which PDE4 inhibitors can selectively bind. Since PDE4 subtypes and isoforms are expressed in specific tissue-, cell type-, and intracellular expression patterns, selective PDE4 subtype/isoform inhibition will enable a more directed modulation of cAMP signaling in the target organ of interest. To further improve PDE4 inhibitor treatment efficacy and safety, it should also be investigated which PDE4 subtypes and isoforms contribute most to the organ's disease-specific aberrant cAMP signaling. Additionally, upon PDE4 specification, the conformational state of these enzymes in their disease context would have to be determined to choose or develop the most efficacious inhibitors (**Figure 5**). Consequently, it is crucial to determine preferential binding of PDE4 inhibitors to specific subtypes, isoforms and conformations rather than testing their affinity towards PDE4 catalytic domains only. Moreover, a deeper insight into the mechanisms underlying PDE4-mediated unwanted effects in organs is also warranted to facilitate the development and use of safe PDE4 inhibitors to treat diseases. In conclusion, specification and subsequent selective inhibition of PDE4 subtypes, isoforms or conformations grants the opportunity to effectively and safely modulate aberrant cAMP signaling in a

myriad of diseases. This will increase the chance of success of more PDE4 inhibitors reaching the patient eventually.

**Figure 5. PDE4 as a pharmacological target in a variety of disease areas.** In a broad range of diseases PDE4 inhibition shows therapeutic potential. Non-selective PDE4 inhibition is associated with adverse effects, but the existence of PDE4 subtypes (PDE4A-D) and associated isoforms allows for more specific targeting. PDE4 subtypes and isoforms can undergo conformational changes upon post-translational modifications and interactions with partner proteins. PDE4 inhibitors can display different affinities towards PDE4 subtypes, isoforms and conformations. Disease-specific determination of which PDE4 isoform(s) should be inhibited will facilitate the development of safe and efficacious PDE4 inhibitors. *Abbreviations: P, phosphorylation; SUMO, SUMOylation.* This figure was created with BioRender.com.

**Increased isoform-specific  
phosphodiesterase 4D (PDE4D) expression  
is associated with pathology and cognitive  
impairment in Alzheimer's disease**

Published as:

Paes et al. (2020) *Neurobiol Aging*. Jan;97:56-64.  
doi: [10.1016/j.neurobiolaging.2020.10.004](https://doi.org/10.1016/j.neurobiolaging.2020.10.004)

## ABSTRACT

Pharmacological phosphodiesterase 4D (PDE4D) inhibition shows therapeutic potential to restore memory function in Alzheimer's disease (AD), but will likely evoke adverse side effects. *PDE4D* encodes multiple isoforms and therefore targeting of specific PDE4D isoforms may improve treatment efficacy and safety. Here, we investigated whether PDE4D isoform expression and *PDE4D* DNA methylation is differentially affected in AD and whether expression changes are associated with severity of pathology and cognitive impairment. In post-mortem temporal lobe brain material from AD patients (n=42) and age-matched controls (n=40), we measured PDE4D isoform expression and *PDE4D* DNA (hydroxy)methylation using qPCR and Illumina 450k Beadarrays, respectively. Linear regression revealed increased expression of PDE4D1, -D3, -D5 and -D8 in AD cases with concurrent (hydroxy)methylation changes in associated promoter regions. Moreover, increased PDE4D1 and -D3 expression was associated with higher levels of tau and plaque pathology, higher Braak stages and more severe cognitive impairment. Future studies should indicate functional roles of specific PDE4D isoforms and the efficacy and safety of their selective inhibition to restore memory function in AD.

## INTRODUCTION

Impaired memory function in Alzheimer's disease (AD) patients has a debilitating effect on daily activities and, consequently, negatively affects the quality of life of patients, their caretakers, and family (Schneider et al., 1999). The second messenger cyclic adenosine monophosphate (cAMP) is crucial in the molecular signaling cascades underlying memory function (Kandel, 2012). Intracellular cAMP levels are mainly controlled through degradation by the phosphodiesterase 4 (PDE4) enzyme family (Houslay, 2010). Accordingly, previous studies have shown that PDE4 inhibition can improve memory consolidation processes in rodents (Vanmierlo et al., 2016). In humans, the PDE4 inhibitor roflumilast was found to enhance verbal learning in young adults and old healthy volunteers (Blokland et al., 2019; Van Duinen et al., 2018). Thus, PDE4 inhibition seems to hold clinical potential as a treatment to enhance memory functioning. The therapeutic potential in AD is supported by the finding that PDE4 inhibition can restore memory impairments induced by intra-hippocampal injections with amyloid  $\beta$  in rats (Cheng et al., 2010). Moreover, in a mouse model of tauopathy, the number of tau aggregates was reduced after administration of the non-selective PDE4 inhibitor rolipram (Myeku et al., 2016). Despite these promising results, progression of new PDE4 inhibitors into the clinic is hampered by the occurrence of dose-limiting side effects; mainly nausea and emesis. More selective inhibition of PDE4 subtypes or isoforms may circumvent these adverse effects. In the present study, we investigated whether expression regulation of PDE4D isoforms is altered in AD brain material to identify potential targets for more selective PDE4 inhibition. The PDE4 family consists of four genes (PDE4A-D) of which *PDE4D* seems to be mostly involved in the modulation of cognitive functions (Zhang et al., 2017). Hence, inhibitors selective for PDE4D have been developed to investigate their cognition-enhancing potential. These new selective PDE4D inhibitors have been found to enhance memory performance in rodents, including models of AD (Ricciarelli et al., 2017; Zhang et al., 2018). The procognitive effects of

PDE4D-specific inhibition are supported by *PDE4D* knock-down studies (Baumgartel et al., 2018). The memory-enhancing potential of PDE4D inhibition has also been tested in Phase I clinical trials (ClinicalTrials.gov Identifier: NCT02648672 and NCT02840279) and currently, preparations are under way to initiate a Phase II trial in patients with early-stage AD (ClinicalTrials.gov Identifier: NCT03817684). Notably, PDE4D inhibition is also hypothesized to induce emetic side effects given its expression in brain areas involved in emesis, i.e. the area postrema, and based on gene deletion studies (Mori et al., 2010; Robichaud et al., 2002). The human *PDE4D* gene gives rise to multiple protein isoforms, i.e. PDE4D1-9, through alternative promoters and alternative splicing. These isoforms regulate a multitude of different processes and are localized to specific compartments within the cell owing to specific amino acids in the N-terminal domain (Houslay, 2010; Houslay et al., 2007). Hence, by inhibiting specific PDE4D isoforms, it can be argued that memory-enhancing effects could be retained without evoking side effects (Schepers et al., 2019). Despite the potential of PDE4D isoform-specific inhibition as a safe and efficacious treatment strategy in AD, the role of PDE4D isoforms in the context of specific brain functions or AD has only sporadically been described (McLachlan et al., 2007; Perez-Torres et al., 2000; Ugarte et al., 2015).

PDE4D isoforms showing high or increased expression in AD could be interesting targets, as these isoforms may contribute largely to cAMP hydrolysis and consequently impede memory functioning. PDE4D isoform expression is likely controlled by epigenetic mechanisms to regulate e.g. isoform-specific promoter accessibility. Previous research indicated that epigenetic modifications at the histone level influence promoter accessibility in the *PDE4D* gene and consequently affect isoform-specific expression in vascular smooth muscle cells (VSMCs) (Tilley and Maurice, 2005). At the nucleotide level, epigenetic processes can reversibly influence transcription through conversion of unmethylated cytosines (UC) into methylated (5mC) or hydroxymethylated (5hmC) cytosines. Specific changes in DNA methylation

and hydroxymethylation have previously been associated with AD (Smith et al., 2019). Recently, *PDE4D* was found those genes displaying differentially methylated in AD in an epigenome-wide association study (Lardenoije et al., 2019).

To investigate whether *PDE4D* isoform expression is altered in AD and whether this is associated with epigenetic changes at specific positions in the *PDE4D* gene, we established *PDE4D* expression and epigenetic profiles of human post-mortem brain material of AD patients and age-matched controls. Since AD is a progressive disease, we also explored whether changes in expression were associated with region-specific plaque and tau load, Braak stage and the degree of cognitive impairment.

## METHODS

### Brain material and study cohort

Informed consent was obtained from all individual participants included in the study. Human post-mortem brain material from the middle temporal gyrus (MTG) of AD patients and neurologically healthy controls was obtained from the Banner Sun Health Research Institute (BSHRI) in Sun City, AZ, USA. For every sample information on Mini-Mental State Examination (MMSE) score (Folstein et al., 1975), gender, age, post-mortem interval (PMI), *APOE*  $\epsilon 4$  possession, amyloid- $\beta$  plaque load, tau tangle load, Braak stage and diagnosis was documented and tissue was prepared by standardized procedures (Beach et al., 2015). Braak staging was evaluated as previously described (Braak and Braak, 1991). AD diagnostic criteria followed guidelines for the National Institute on Aging (NIA)-Reagan Institute criteria (The National Institute on Aging, and Reagan Institute Working Group on Diagnostic Criteria for the Neuropathological Assessment of Alzheimer's Disease, 1997) combined with clinical diagnosis reports. Samples collected after a PMI of more than 5 hours and samples from patients with comorbidities were excluded. A total of 82

samples were included from AD patients (n=42) and age- and gender-matched neurologically healthy controls (n=40) with an average PMI of 2.8 hours. For subsequent analysis investigating associations between expression and MMSE score, cases for which cognitive performance in the MMSE was assessed longer than 36 months before death were excluded, leaving a subset of 41 cases. A detailed description of the cohort demographics can be found in Table 1.

**Table 1.** Demographic characteristics of the cohort

Characteristic	Non-demented controls	AD patients
<b>Gender</b> (male/female)	20/20	19/23
<b>APOE ε4</b> (present/absent)	9/31	27/15
<b>Braak stage</b> (I-II/III-IV/V-VI)	16/24/0	0/14/28
<b>Age</b> mean (SD)	84.3 (5.81)	85.1 (6.49)
<b>PMI</b> mean (SD)	2.77 (0.75)	2.75 (0.73)

### RNA isolation, cDNA synthesis and qPCR

Total RNA was isolated from frozen MTG tissue using the TRIzol® Plus RNA Purification Kit (Life Technologies, Carlsbad, CA) following the manufacturer's protocol. Isolated RNA pellets were dissolved in RNase-free water and assessed for quantity and quality (average RIN: 9.1) using a Nanodrop ND-1000 spectrophotometer (Thermo Scientific, DE, USA) and Bioanalyzer (Agilent). Then, cDNA was synthesized using the Revert Aid First Strand Synthesis Kit (Thermo Scientific, Landsmeer, Netherlands) according to the manufacturer's protocol.

TaqMan based qPCR primers were used for the following PDE4D isoforms: PDE4D2, PDE4D4, PDE4D5, PDE4D6, PDE4D8 and PDE4D9 (Applied Biosystems, Foster City, California, USA). PDE4D2 could not be detected. Primers were designed for PDE4D1, PDE4D3 and PDE4D7 as no TaqMan-based qPCR primers were available for these isoforms (SIGMA Life Science). Housekeeping gene expression of *EIF4A2* and *TOP1* showed the most stable expression based on geNorm criteria and was

used for normalization (Vandesompele et al., 2002). TaqMan probe and primer sequences are listed in Table 2. TaqMan based qPCR was performed using TaqMan Assay 20x and TaqMan Universal Master Mix II, with UNG 2x (Applied Biosystems, Foster City, California, USA) following the manufacturer's protocol. For qPCR using primers, SensiMix 2X (Bioline), was used according to the manufacturer's protocol. All reactions were performed using 6 ng cDNA on a LightCycler 480 (Roche).

**Table 2.** TaqMan probe and primer sequences.

Isoform	Forward primer (5'-3')	Reverse primer (5'-3')
PDE4D1	AGAACTGAGTCCCCCTTCC	TGAGCTCCCGATTAAGCATC
PDE4D3	CCACGATAGCTGCTCAAACA	GTGCCATTGTCCACATCAAA
PDE4D7	GAACATTCAACGACCAACCA	TTCGGGACATAGACTTTGG
EIF4A2	GGTCAGGGTCAAGTCGTGT	CCCCTCTGCCAATTCTGTGA
TOP1	CCCTGTACTTCATCGACAAGC	CCACAGTGTCGCTGTTC
Isoform	TaqMan probe sequence (5'-3')	TaqMan Assay ID
PDE4D2	TCCGAGCATGGCGGGAGGAGGCCTA	Rn01494075_g1
PDE4D4	TTCCAGGGACTCAGGCGTTTTGATG	Hs01588302_m1
PDE4D5	CACATACATGTTTTGATGTGGACAA	Hs01588303_m1
PDE4D6	ATAAAGTTTAAAAGGATGCTTAATC	Hs01572151_m1

PDE4D9	GCAGTTTGTGTTGATGTGGACAATG	Hs01572149_m1

### Tissue preparation for (hydroxy)methylomic profiling

DNA was isolated from the MTG at the BSHRI. From 81 of the 82 subjects, a total of 76 mg of frozen tissue was obtained (Beach et al., 2015). Tissue was digested at 55°C in lysis buffer (100 mM Tris HCl pH 8.5, 200 mM NaCl, 5 mM EDTA, 100 µg/ml Proteinase K [Sigma-Aldrich, St. Louis, Missouri, USA], and 0.2% SDS) and homogenized in a pellet mixer (Kontes). After addition of RNase (Qiagen, Valencia,

California, USA), DNA was isolated by means of phenol/chloroform (Sigma) extraction followed by ethanol precipitation and resuspension in TE buffer (pH 8.0). Ultimately, DNA samples were quantified and checked for purity by means of spectrophotometry.

### **Oxidative bisulfite conversion and DNA (hydroxy)methylation assay**

The (oxidative) bisulfite conversion procedures and HumanMethylation450 BeadChip array were carried out at ServiceXS (ServiceXS B.V., Leiden, the Netherlands), in accordance to the manufacturer's protocols and as described previously (Lardenoije et al., 2019). Briefly, A TrueMethyl™ 24 kit version 2.0 by CEGX™ (Cambridge Epigenetix Limited, Cambridge, UK) was used to convert the isolated genomic DNA (gDNA) by bisulfite (BS) or oxidative bisulfite (oxBS) treatments to detect and localize 5mC and 5hmC marks at single-base resolution. Before conversion, gDNA quality was assessed using a PicoGreen assay (Invitrogen, Carlsbad, California, USA) and high molecular weight gDNA (HMW-gDNA) was quantified by gel-electrophoresis. Upon purification and denaturation, HMW-gDNA (0.5 µg per treatment) was used for DNA oxidation or mock DNA oxidation treatments followed by bisulfite conversion. DNA yield was assessed by Qubit ssDNA assay (Invitrogen) and qualitative assessment of 5hmC oxidation and bisulfite conversion was performed using a restriction quality control. Then, 8 µl of each DNA sample was used for amplification and hybridization on the HumanMethylation450 BeadChip (Illumina, Inc., San Diego, CA, U.S.A.) according to the Illumina 'Infinium II Methylation Assay Manual' protocol. Eventually, the Illumina iScan was used to scan the samples.

### **Processing of DNA (hydroxy)methylation assay data**

For (hydroxy)methylomic profiling, data was processed and analyzed using R statistical programming language (version 3.5.3)(R Development Core Team, 2019) and RStudio (version 1.2.1335)(RStudio Team, 2019). The minfi package (version

1.28.4) was used to load raw IDAT files from the Illumina iScan(Aryee et al., 2014). Probes that cross-hybridize, locate to X and Y chromosomes and probes binding within 10 bp of a common SNP location were removed (Chen et al., 2013). Remaining probes were filtered using the 'pfilter' function of the waterMelon package (version 1.26.0) (6,414 probes were removed)(Pidsley et al., 2013). Data from 397,160 remaining probes were split into two sets of beta values according to the oxBS and BS arrays, representing 5mC and 5mC+5hmC, respectively. These data were *dasen* normalized using the waterMelon package (Pidsley et al., 2013). The maximum likelihood methylation levels (MLML) method was used, by means of the 'MLML' function within the MLML2R package (version 0.3.2), to calculate the proportions of 5mC, 5hmC and UC by combining the signal from the BS and oxBS arrays as input(Kiuhl et al., 2019; Qu et al., 2013). Subsequently, probes showing either a 5hmC value of zero in at least half of the cases or BS beta value lower than 0.1 were filtered out (112,697 5hmC values were excluded). Data distributions of raw and normalized beta values per sample were visualized in boxplots and density plots to identify outliers (3 samples were excluded due to clear deviation from the other samples; data not shown). Data were processed again upon removal of these outliers.

After data processing, 78 samples remained, with 397,160 remaining probes for 5mC and UC, and 284,463 5hmC probes. Data were split into two sets of beta values according to the oxBS and BS arrays, representing 5mC and 5mC+5hmC, respectively.

## **Statistical Analysis**

Raw expression data from the LightCycler 480 were analyzed using LinRegPCR to determine logarithmic fluorescence values at cycle zero (Ruijter et al., 2009). qPCR reactions that did not show fluorescent signal amplification were excluded from further analysis. Logarithmic fluorescence values were normalized

against the average expression of reference genes *TOP1* and *EIF4A2*. Normalized data followed a Gaussian distribution and were used for statistical analysis.

For expression data, linear regression analyses were performed using IBM SPSS Statistics for Windows, Version 25.0 (IBM Corp., Armonk, United States) with normalized starting fluorescence values per isoform as dependent variable and diagnosis (control = 0, AD = 1, respectively), plaque load in the temporal lobe (0-3), tangle load in the temporal lobe (0-3), Braak stage level (Braak I-II = 0, Braak III-IV = 1, and Braak V-VI = 2) or MMSE score (0-30) as independent variable. Age, gender, PMI, *APOE*  $\epsilon$ 4 possession and qPCR plate were included as covariates. Unstandardized regression coefficients were exponentially transformed to calculate the fold expression change in AD. P values were Bonferroni-corrected by multiplying P values by the number of dependent variables (i.e. expression of isoforms) tested per model, and values smaller than 0.05 were considered statistically significant.

For (hydroxy)methylomic data, a surrogate variable (SV) analysis was done with the *sva* package (version 3.30.1)(Leek et al., 2012) on an initial linear regression model with beta values as dependent variable, diagnosis as independent variable, and age, gender, PMI and *APOE*  $\epsilon$ 4 possession as covariates. To adjust for unobserved confounders, the first five SVs of the SV analysis were included in the regression model. Linear regression was performed using the *limma* package (version 3.38.3)(Ritchie et al., 2015). Adjustment for bias and inflation of test statistics was done with the *bacon* package (version 1.10.1)(van Iterson et al., 2017). To explore whether isoform-specific expression changes could be mechanistically explained by specific epigenetic changes, only probes that locate closest to *PDE4D* isoform promoters showing significant expression changes (i.e. *PDE4D1*, -D3, -D5 and -D8) were selected (24 probes). Nominal significance for DNA methylation changes between AD cases and controls was set at  $P$ -value < 0.05. Diagnosis-associated methylation changes were investigated further by follow-up linear regression analyses using the same model, but instead of diagnosis, using plaque load in the

temporal lobe (0-3), tangle load in the temporal lobe (0-3), Braak stage level (Braak I-II = 0, Braak III-IV = 1, and Braak V-VI = 2) or MMSE score (0-30) as predictor variable. False discovery rates (FDR) for these predictors' P values were determined by the Benjamini-Hochberg procedure.

## RESULTS

### Increased PDE4D isoform expression in Alzheimer's disease

Linear regression analyses revealed that AD diagnosis was significantly associated with increased expression levels of PDE4D1, -D3, -D5, and -D8, in the range of 2.56-3.85 fold increased expression ( $P < 0.05$ ; Table 3).

**Table 3.** PDE4D isoform expression in MTG tissue from AD patients compared to controls.

<b>Isoform expression</b>	<b>N</b>	<b>Diagnosis standardized coefficient</b>	<b>P-value Bonferroni-corrected</b>	<b>Fold change in AD</b>
PDE4D1	82	0.383	0.013	2.99
PDE4D3	82	0.435	0.002	3.85
PDE4D4	67	0.259	0.487	2.14
PDE4D5	67	0.356	0.040	2.56
PDE4D6	77	0.267	0.257	2.90
PDE4D7	82	0.309	0.091	2.82
PDE4D8	62	0.394	0.045	3.85
PDE4D9	77	0.249	0.212	2.24

Linear regression analyses were performed according to the following formula: Expression = Intercept + Diagnosis + Gender + Age + APOE  $\epsilon$ 4 possession + PMI + qPCR plate. Significance levels are Bonferroni-corrected for the number of dependent variables tested. P values and fold changes are rounded to three and two decimals, respectively.

## Differential epigenetic signatures in *PDE4D* promoter regions in Alzheimer's disease

As *PDE4D* was found to be differentially methylated in AD in an epigenome-wide association study using the same tissue (Lardenoije et al., 2019), as an exploratory approach, we investigated whether CpG sites within the promoter regions of differentially expressed *PDE4D1*, *-D3*, *-D5*, *-D8* were subject to methylation differences. Twenty-four of the EWAS assay probes located to these promoters allowed the assessment of the methylation status (5mC, 5hmC or UC) of specific CpG sites. Linear regression analyses revealed diagnosis-dependent methylation status differences in each of the promoters. The CpG sites for which methylation status was associated with diagnosis are shown in Table 4. AD-associated effects on methylation status appear to be different per promoter region. For example, in the *PDE4D3* promoter, at position cg13112511, AD diagnosis was associated with decreased 5mC (fold change [FC] = .9818,  $P < 0.05$ ) and increased 5hmC (FC = 1.0197,  $P < 0.05$ ) levels. Contrastingly, increased 5mC (FC = 1.0144,  $P < 0.01$ ) and decreased 5hmC (FC = .9812,  $P < 0.05$ ) levels were found in the *PDE4D8* promoter at cg23987137 in AD cases. Within the *PDE4D5* promoter, effects with opposite directionality were found; increased 5mC and decreased UC levels were detected in AD cases at position cg03653541 (5mC: FC = 1.0023,  $P < 0.05$  and UC: FC = .9972,  $P < 0.05$ ), while position cg14784398 indicated decreased 5mC (FC = .9958,  $P < 0.05$ ) and increased UC (FC = 1.0035,  $P < 0.05$ ) levels. These findings suggest that AD is associated with *PDE4D* DNA (hydroxy)methylation changes that are promoter- and site-specific, concomitant with expression changes of the corresponding isoforms.

**Table 4.** CpG sites in PDE4D promoter regions showing altered methylation status in AD.

Promoter	N	CpG probe	Status	Fold change in AD	Mean	t	df	P-value
PDE4D1	78	cg19539826	UC	0.9871	0.5871	-2.363	67	0.018
PDE4D3	78	cg13112511	5mC	0.9818	0.3211	-2.571	67	0.010
	78	cg13112511	5hmC	1.0197	0.0537	2.299	67	0.022
PDE4D5	78	cg03653541	5mC	1.0023	0.0729	2.402	67	0.016
	78	cg14784398	5mC	0.9958	0.1267	-2.330	67	0.020
	78	cg12519013	5mC	0.9965	0.0849	-1.970	67	0.049
	78	cg14784398	UC	1.0035	0.8722	2.098	67	0.036
	78	cg03653541	UC	0.9972	0.9178	-2.010	67	0.044
PDE4D8	78	cg23987137	5mC	1.0144	0.3957	2.833	67	0.006
	78	cg23987137	5hmC	0.9812	0.1765	-2.391	67	0.017
	78	cg17584009	5hmC	1.0162	0.2300	1.961	67	0.050

Linear regressions were performed according to the following formula: Methylation status = Intercept + Diagnosis + Gender + Age + APOE ε4 possession + PMI + five surrogate variables.

Abbreviations: df, degrees of freedom; UC, unmethylated cytosine; 5mC, 5-methylcytosine; 5hmC, 5-hydroxymethylcytosine.

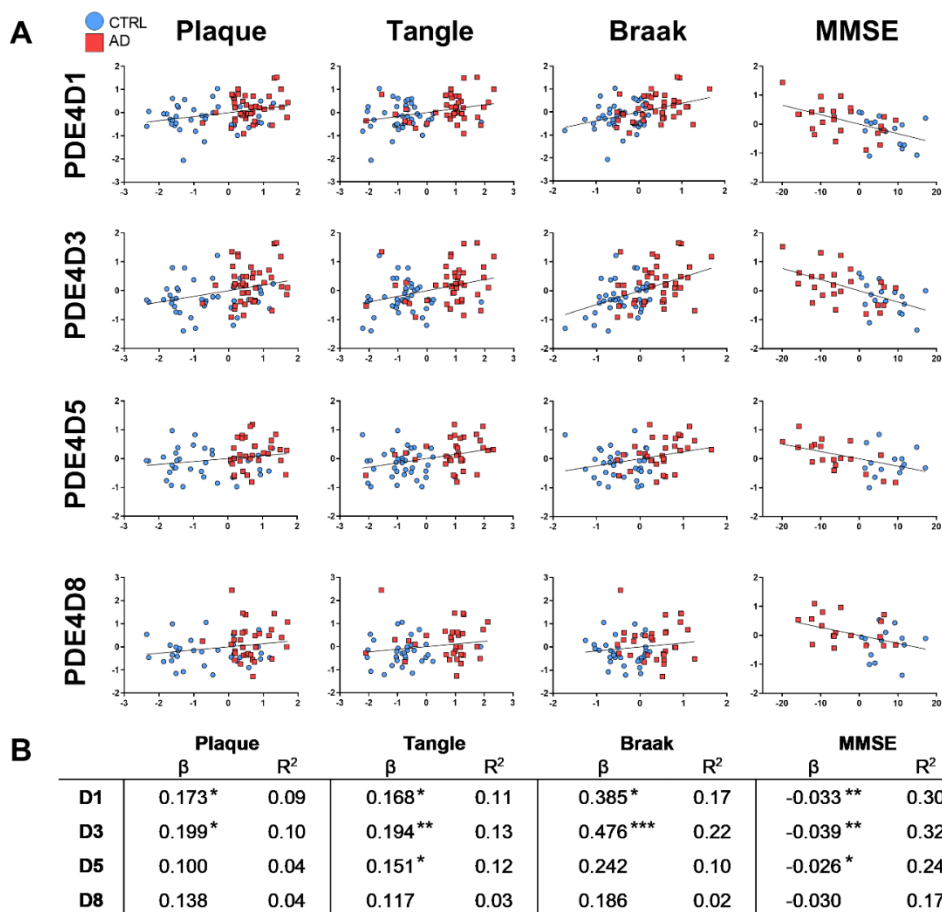

## PDE4D isoform expression is associated with AD pathology and cognitive impairment

For isoforms showing different expression between AD and controls (i.e. PDE4D1, -D3, -D5 and -D8), linear regression analyses were performed to investigate whether expression was associated with the degree of pathology or cognitive impairment. Higher levels of plaque pathology in the temporal lobe were associated with increased PDE4D1 and -D3 expression ( $P < 0.05$ ), while tangle pathology in the temporal lobe was associated with increased expression of PDE4D1 ( $P < 0.05$ ), PDE4D3 ( $P < 0.01$ ) and PDE4D5 ( $P < 0.05$ ; Table 5 and Figure 1). In addition, Braak staging associated significantly with increased expression of PDE4D1 ( $P < 0.05$ ) and PDE4D3 ( $P < 0.001$ ). Additionally, we examined the association between isoform expression and the level of cognitive impairment as assessed by the MMSE. Lower MMSE scores were significantly associated with increased expression of PDE4D1 ( $P < 0.01$ ), PDE4D3 ( $P < 0.01$ ) and PDE4D5 ( $P < 0.05$ ; Table 5 and Figure 1). These results indicate that increased expression, of mainly the PDE4D1 and PDE4D3 isoforms, correlates with higher pathology levels and more severe cognitive impairment.

**Table 5.** Association of pathology and cognitive impairment level with PDE4D isoform expression.

Dependent variable		Standardized coefficient per pathology variable			Standardized coefficient for MMSE	
Isoform	N	Plaque load	Tangle load	Braak stage	N	MMSE
PDE4D1	82	0.313*	0.352*	0.445*	41	-0.577**
PDE4D3	82	0.332*	0.374**	0.508***	41	-0.610**
PDE4D5	67	0.207	0.344*	0.315	33	-0.475*
PDE4D8	62	0.211	0.203	0.178	32	-0.448

Linear regressions were performed according to the following formula: Expression = Intercept + Pathology variable (i.e. plaque load, tangle load, Braak) or MMSE + Gender + Age + ApoE allele  $\epsilon 4$  possession + PMI + qPCR plate. Cases for which MMSE scores were assessed more than 36 months before death were excluded. Significance levels Bonferroni-corrected for the amount of dependent variables tested; \*:  $p < 0.05$ , \*\*:  $p < 0.01$ , \*\*\*:  $p < 0.001$ .

**Figure 1. Association of pathology and cognitive impairment level with PDE4D isoform expression.**

A) Partial regression plots visualizing the associations between PDE4D isoform expression and the degree of pathology (plaque and tangle load in the temporal lobe, and Braak stage level) or cognitive impairment (MMSE score), corrected for gender, age, ApoE allele  $\epsilon 4$  possession, PMI and qPCR plate. Marker types reflect the diagnosis status of the cases (blue circles: controls, red squares: AD cases). B) Overview of slope values ( $\beta$ ) and squared correlation coefficients of the regression lines in the partial regression plots in panel A.  $\beta$  values correspond to the unstandardized coefficients of pathology and MMSE variables in the regressions according to the formula described in Table 5. Significance levels Bonferroni-corrected for the amount of dependent variables tested; \*,  $p < 0.05$ , \*\*,  $p < 0.01$ , \*\*\*,  $p < 0.001$ .

## ***PDE4D* promoter methylation is associated with AD pathology and cognitive impairment**

The diagnosis-dependent methylation changes as determined in Table 4 were investigated further for their potential association with the degree of pathology or cognitive impairment by means of linear regression analyses. These analyses revealed significant associations between methylation status changes and pathology or cognitive impairment in accordance to the directionality of changes observed between AD cases and controls. In the *PDE4D3* promoter, both decreased 5mC (hypomethylation) and increased 5hmC (hyperhydroxymethylation) at CpG site cg13112511 were found to associate with an increased plaque load and a higher Braak stage (Table 6). Contrarily, in the *PDE4D8* promoter, increased 5mC and decreased 5hmC at position cg23987137 was associated with increased pathology levels. Methylation status in the *PDE4D5* promoter also associated with levels of pathology but the directionality of methylation status change was different per CpG site (e.g. cg03653541 shows increased 5mC, whilst cg12519013 shows decreased 5mC with higher levels of pathology; Table 6). Lastly, lower MMSE scores were associated with increased 5mC levels in the *PDE4D5* promoter (cg03653541) and *PDE4D8* promoter (cg23987137).

**Table 6.** Significant associations of PDE4D promoter methylation status with pathology and cognitive impairment.

Promoter	CpG probe	Status	N	Variable	Fold change	Mean	t	df	P-value	FDR
PDE4D3	cg13112511	5mC	78	Plaque	0.9917	0.3211	-2.561	67	0.010	0.017
			78	Braak	0.9858	0.3211	-2.929	67	0.003	0.008
		5hmC	78	Plaque	1.0095	0.0537	2.456	67	0.014	0.042

			78	Braak	0.9851	0.1765	-2.735	67	0.006	0.019

Linear regressions were performed according to the following formula: Methylation status = Intercept + Pathology variable (i.e. plaque load, tangle load, Braak) or MMSE + Gender + Age + APOE ε4 possession + PMI + five surrogate variables. Cases for which MMSE scores were assessed more than 36 months before death were excluded. Abbreviations: df, degrees of freedom; FDR, false discovery rate (Benjamini-Hochberg); UC, unmethylated cytosine; 5mC, 5-methylcytosine; 5hmC, 5-hydroxymethylcytosine.

## DISCUSSION

Inhibition of PDE4D has been shown to hold promise as an effective strategy to enhance memory in humans (clinical trials NCT02648672 and NCT02840279), but is also assumed to contribute to possible emetic side effects upon non-selective PDE4 inhibition (Giembycz, 2002; Mori et al., 2010). The *PDE4D* gene encodes multiple isoforms that, e.g. by specific intracellular localization, can regulate different compartmentalized pools of cAMP (Houslay et al., 2007). Hence, targeting specific PDE4D isoforms may provide a safer and more efficacious treatment strategy to alleviate memory deficits in AD without evoking side effects (Schepers et al., 2019). To investigate which specific PDE4D isoform(s) is/are altered in terms of expression in AD, we established PDE4D isoform expression profiles in post-mortem MTG tissue derived from AD patients and healthy non-demented controls by means of isoform-specific qPCR.

Regression analyses revealed that AD was associated with increased expression of PDE4D1, -D3, -D5 and -D8. Expression of these isoforms was increased in the range of 2.56-3.85 fold. Previous studies have indicated that 3-4 fold increased PDE4D (isoform) mRNA expression results into similar increases in both PDE4D protein expression and PDE4 activity (Levallet et al., 2007; Peter et al., 2007). Therefore, the 2.59-3.85 fold expression increases likely increase PDE4 activity. To our knowledge, the number of studies investigating PDE4D expression in light of AD is limited. Ugarte et al. did not find a difference in overall PDE4D expression in temporal lobe material from AD patients (n=7) and controls (n=8) (Ugarte et al., 2015). McLachlan et al. investigated hippocampal PDE4D isoform expression in material from a single patient with advanced AD and three control cases and found a 2.62-fold increase in PDE4D1 expression, while the expression of other isoforms was reduced or unaffected (McLachlan et al., 2007). Our study, making use of a much larger sample size, shows, in addition to a similar increase in PDE4D1 expression,

increased expression of PDE4D3, -D5 and -D8. The current findings imply that PDE4D expression is affected in AD in an isoform-specific manner.

Since AD is a progressive disease, we also inspected whether PDE4D isoform expression increases with higher degrees of pathology or more severe cognitive impairment. Expression of PDE4D1 and PDE4D3 was associated with temporal plaque load, temporal tangle load, Braak staging as well as cognitive impairment. PDE4D5 expression was found to be only associated with temporal tangle load and cognitive impairment, while PDE4D8 expression was not associated with any pathology measure or cognitive impairment. These findings suggest that mainly PDE4D1 and PDE4D3 expression changes as the disease progresses and cognitive impairment worsens. The observation that PDE4D3 transcription is increased in presence of higher amyloid- $\beta$  plaque load corresponds to earlier findings. Hippocampal injections of A $\beta$ <sub>1-42</sub> in mice caused memory deficits and increased protein expression of PDE4D3, which was reversed upon non-selective PDE4 inhibition by resveratrol (Wang et al., 2016). Interestingly, Oláh et al. found a direct interaction between oligomeric A $\beta$  and PDE4D (Olah et al., 2011). Whether this interaction occurs *in vivo* and how this interaction affects PDE4D enzymatic activity remains to be determined. From a potentially therapeutic perspective, it would be interesting to identify whether inhibition of PDE4D1 and/or PDE4D3 specifically can delay disease progression and improve cognitive functioning.

As the *PDE4D* gene, with its various isoforms embedded, contains multiple promoter regions, epigenetic mechanisms are likely involved in its isoform-specific expression regulation, e.g. by influencing promoter accessibility (Maunakea et al., 2010; Tilley and Maurice, 2005). Here, we found that DNA (hydroxy)methylation signatures in the promoter regions of PDE4D1, -D3, -D5 and -D8 were altered in the same tissue as used for the expression profiling. Results showed differentially methylated CpG sites in these promoters that were associated with AD diagnosis. Moreover, methylation status was also associated with the degree of pathology and

cognitive impairment for several CpG sites. Various effects were observed, i.e. both increased and decreased 5mC, 5hmC and UC levels. Differences in methylation and hydroxymethylation can be linked to altered gene expression by affecting the binding of transcription factors and chromatin proteins to the DNA (Suzuki and Bird, 2008; Yin et al., 2017). As such, decreased methylation and increased hydroxymethylation in AD in the PDE4D3 promoter might explain, at least in part, the observed pathology- and AD-associated increased expression of PDE4D3. In contrast, in the PDE4D8 promoter, cg23987137 displayed AD-associated hypermethylation and hypohydroxymethylation. However, cytosine methylation can have differential effects on transcription factor binding and subsequent gene expression. Interestingly, cg23987137 is located 14 nucleotides downstream of an AP-1 binding site (Farre et al., 2003). The transcription factor AP-1 is usually described as a transcriptional activator, but can also act as transcriptional repressor (Brellier et al., 2004). Moreover, it has been shown that methylation adjacent to, but not within, the AP-1 binding site can hamper AP-1 binding and consequently induce transcription (Fujimoto et al., 2005). Although purely speculative, a similar mechanism might affect transcription near the PDE4D8 promoter resulting in increased expression upon CpG site hypermethylation. Similarly, epigenetic changes observed in the other promoters can, by influencing binding of transcriptional activators and repressors, induce increased expression of the associated isoforms. Interestingly, increased methylation at cg23987137 PDE4D8 promoter was associated with worse cognitive performance whilst PDE4D8 expression did not associate with cognitive performance. This discrepancy may suggest that DNA methylation may not solely influence expression via its closest located promoter but may also regulate expression of other isoforms which do show associations with cognitive performance (i.e. PDE4D1, -D3 and -D5).

The current findings show that in AD, expression of specific PDE4D isoforms is altered with concurrent changes (hydroxy)methylation changes in associated

promoters of the *PDE4D* gene. Although PDE4D isoforms locate to specific cellular compartments, the role of individual PDE4D isoforms in specific cellular processes is still largely unknown. The mouse orthologue of PDE4D1 is reported to localize to the nucleus (Chandrasekaran et al., 2008). With 95.6% homology in the N-terminal, human PDE4D1 may share a similar localization signal and hence could be involved in the regulation of nuclear cAMP levels which may directly affect PKA-CREB mediated transcription crucial for memory consolidation (Kandel, 2012). Transgenic overexpression of PDE4D1 in specific neurons was found to decrease  $Ca^{2+}$  oscillations, which may imply a specific role for this isoform in neuronal firing (Yoshida et al., 2003). Increased PDE4D1 expression in AD may therefore decrease neuronal firing rates that subsequently impacts neuronal plasticity and memory formation processes.

Specific interactions have been reported between PDE4D3 and A-kinase anchoring proteins (AKAPs), e.g., AKAP9 and mAKAP $\alpha$ , through which PDE4D3 can locally degrade cAMP pools (Boczek et al., 2019; Terrenoire et al., 2009). Disrupting the perinuclear PDE4D3- mAKAP $\alpha$  signaling complex promoted survival and axon growth in neurons (Boczek et al., 2019). Vice versa, increased PDE4D3 expression as observed in the current study could hamper these effects, thereby likely impairing neuronal plasticity and memory processes in AD.

Similar to PDE4D3-AKAP interactions, the scaffolding protein  $\beta$ -arrestin was found to preferentially interact with PDE4D5 (Baillie et al., 2007).  $\beta$ -arrestin is recruited to G-protein coupled receptors (GPCRs) upon activation, which places PDE4D5 in close proximity to sites where cAMP is produced, i.e. close to GPCRs and activated adenylyl cyclases that produce cAMP (Baillie et al., 2003; Houslay and Baillie, 2005). Increased PDE4D5 levels may therefore excessively degrade cAMP at the site of synthesis. Vice versa, downregulation of PDE4D5 may stimulate cAMP signaling, which is supported by the interesting finding that knockdown of PDE4D4 or PDE4D5 can improve memory performance in mice (MacKenzie et al., 2011; Wang et al., 2013). In addition

to cytosolic interactions, it was found that PDE4D5 also regulates cAMP levels in nuclear signaling complexes, indicating that a specific isoform can regulate cAMP levels in spatially distinct compartments (Clister et al., 2019).

Regarding PDE4D8, most insights have been gathered through cardiovascular research. In cardiomyocytes, PDE4D8 is located near the  $\beta$ 1-adrenergic receptor through a SAP97-mediated interaction and dissociates upon receptor stimulation (Fu et al., 2014; Richter et al., 2008). As SAP97 is a synapse-associated protein that scaffolds multiple receptors, including AMPA receptors crucial for memory processes, similar interactions may occur in the brain (Zhang et al., 2015). Moreover, PDE4D8 is found to localize in leading-edge structures of migrating vascular smooth muscle cells and affects actin organization upon overexpression (Raymond et al., 2009). Actin-rich leading edges in neuronal or glial cells may also be affected by increased PDE4D8 levels and consequently induce dysfunctional migration and growth, possibly contributing to impaired cognitive functioning eventually.

Through their specific localizations, the isoforms PDE4D3, -D5 and -D8 have all been reported to modulate downstream signaling of  $\beta$ -adrenergic receptors (Baillie et al., 2003; De Arcangelis et al., 2009; Richter et al., 2008). As adrenergic signaling is involved in cognitive functioning and can be affected in AD (Gannon et al., 2015), changes in expression of PDE4D isoforms may disrupt downstream  $\beta$ -adrenergic signaling leading to cognitive dysfunction. In sum, upcoming studies will have to indicate isoform-specific roles in memory processes, so local cAMP compartments can be targeted and treatment efficacy can be increased.

Lastly, the current findings represent PDE4D isoform expression and DNA (hydroxy)methylation in homogenized brain tissue, meaning no conclusions can be drawn yet on potential cell type-specific effects. Hence, follow-up studies will have to indicate whether the current findings can be linked to changes in specific cell types

(e.g., neurons, microglia, astrocytes, oligodendrocytes, endothelial cells). Also, whether increased PDE4D expression is causal to or a consequence of worsening pathology remains to be specified. Nevertheless, these findings highlight isoform-specific PDE4D inhibition as a potential strategy to aid in delaying disease progression with associated procognitive effects.

## **CONCLUSION**

Taken together, regulation of PDE4D transcription is affected in AD as indicated by differences in gene (hydroxy)methylation and expression levels. Moreover, the specific isoforms PDE4D1 and PDE4D3 show a significant association with the degree of pathology and cognitive impairment. In line with the fact that PDE4D isoforms regulate specific intracellular processes, this implies that targeting specific PDE4D isoforms may provide a more efficacious treatment strategy with less adverse effects in different stages of the disease. For this purpose, future studies will have to reveal which PDE4D isoforms regulate mechanisms underlying memory enhancement and do not show adverse effects upon inhibition in the context of brain function in both health and AD.

## **ACKNOWLEDGEMENTS**

This work was financially supported by grants from ISAO/Alzheimer Nederland WE.03-2016-07, Young European Research Universities Network (YERUN) and the Baeter Laeve foundation. Additional funds have been provided by the Internationale Stichting Alzheimer Onderzoek (ISAO) / Alzheimer Netherlands (Award #11532; Funded by the Dorpmans-Wigmans Foundation) (DvdH), and by the Joint Programme—Neurodegenerative Disease Research (JPND) for the EPI-AD consortium ([http://www.neurodegenerationresearch.eu/wp-content/uploads/2015/10/Factsheet EPI-AD.pdf](http://www.neurodegenerationresearch.eu/wp-content/uploads/2015/10/Factsheet_EPI-AD.pdf)). The project is supported through the following funding organizations under the aegis of JPND; The Netherlands, The Netherlands Organisation for Health Research and Development (ZonMw); United Kingdom, Medical Research Council; Germany, German Federal Ministry of Education and Research (BMBF); Luxembourg, National Research Fund (FNR). This project has received funding from the European Union's Horizon 2020 research and innovation programme under Grant Agreement No. 643417.

We thank Dr. Ir. Jochen De Vry for primer and qPCR experiment design.

## **DISCLOSURE STATEMENT**

TV and JP have a proprietary interest in selective PDE4D inhibitors for the treatment of neurodegenerative disorders. The other authors declare that they have no competing interests.

## ABSTRACT

Inhibition of phosphodiesterase 4D (PDE4D) enzymes has been investigated as a therapeutic strategy to treat memory problems in Alzheimer's disease (AD). Although PDE4D inhibitors are effective in enhancing memory processes in rodents and humans, severe side effects may hamper their clinical use. PDE4D enzymes comprise different isoforms, which, when targeted specifically, can increase treatment efficacy and safety. The role of PDE4D isoforms in AD and in molecular memory processes per se has remained unresolved. Hippocampus and prefrontal cortex were harvested from APP<sup>swe</sup>/PS1<sup>dE9</sup> transgenic mice. Differences in PDE4D, PKA and pCREB protein levels and PDE4 activity were assessed by means of Western blot and activity assays, respectively (two-tailed t-test). The effect of amyloid- $\beta$  exposure on PDE4D isoform expression was evaluated using qPCR in the *ex vivo* mouse brain material and in mouse hippocampal neurons. Moreover, using these neurons, the effects of the PDE4D-selective inhibitor GEBR32a and PDE4D isoform knockdown using CRISPR-Cas9 on neurite outgrowth were assessed, both with and without exposure to amyloid- $\beta$  (Dunnett's post hoc t-test). We report the upregulation of specific PDE4D isoforms in transgenic AD mice and hippocampal neurons exposed to amyloid- $\beta$ . Furthermore, by means of pharmacological inhibition and CRISPR-Cas9 knockdown, we demonstrate that inhibition of the long-form PDE4D3, -D5, -D7, and -D9 isoforms enhances neuronal plasticity and conveys resilience against amyloid- $\beta$  induced decreases in neuroplasticity *in vitro*. These results indicate that isoform-specific ablation, next to non-selective PDE4D inhibition is efficient in promoting neuroplasticity in an AD context. Therapeutic effects of non-selective PDE4D inhibitors are likely achieved through actions on long isoforms. Future research should identify which long PDE4D isoforms should be specifically targeted *in vivo* to improve treatment efficacy and reduce side effects.

## INTRODUCTION

Memory consolidation deficits associated with Alzheimer's disease (AD) cause severe impairment in AD patients, and place a tremendous burden on their caretakers and family members. Hence, pharmacological interventions that stimulate the molecular machinery underlying memory consolidation would improve the quality of life of AD patients and people close to them. Cyclic adenosine monophosphate (cAMP) plays a pivotal role as second messenger in signaling cascades that regulate memory consolidation (Kandel, 2012). Enzymatic degradation of cAMP predominantly occurs by phosphodiesterase 4 (PDE4) enzymes (Houslay, 2010). Consequently, inhibition of PDE4 would promote cAMP signaling and associated memory consolidation processes (Blokland et al., 2019a). Accordingly, PDE4 inhibition has been found to enhance memory functioning in both rodents and healthy humans (Blokland et al., 2019b; Van Duinen et al., 2018; Vanmierlo et al., 2016). In addition, PDE4 inhibition has shown pro-cognitive effects in AD animal models (Ashour et al., 2021; Cheng et al., 2010; Feng et al., 2019; Myeku et al., 2016; Schepers et al., 2019; Wang et al., 2020).

Despite the therapeutic potential of PDE4 inhibitors to restore memory functioning in AD, clinical use is hindered due to severe side effects such as nausea and emesis (Paes et al., 2021). Interestingly, the PDE4 enzyme family is encoded by four genes (*PDE4A-D*), each producing a sub-family comprising of several isoforms (e.g. PDE4D1-9). By specific inhibition of PDE4 sub-families or isoforms rather than non-selective PDE4 inhibition, adverse effects may be minimized or prevented (Bhat et al., 2020; Blokland et al., 2019a; Paes et al., 2021). The PDE4D subtype has shown to be a promising target for memory enhancement. In a recent exploratory study, PDE4D expression in blood was found to negatively correlate with cognitive function in monozygotic twins (Mohammadnejad et al., 2021). Moreover, *PDE4D* gene variants affect functional brain networks in patients with mild cognitive impairment and AD (Xiang et al., 2020). In rodents, inhibition of PDE4D, rather than PDE4B, was

found to enhance memory functioning (Zhang et al., 2017). Moreover, in AD mouse models, pharmacological inhibition or shRNA-mediated knockdown of PDE4D has been reported to restore amyloid- $\beta$  (A $\beta$ ) induced memory deficits (Cui et al., 2019; Shi et al., 2021b; Sierksma et al., 2014; Zhang et al., 2014).

While PDE4D is a promising target to restore AD-associated memory deficits, inhibition of the PDE4D sub-family has been associated with the onset of side effects similar to those caused by non-specific PDE4 inhibitors when compared to non-specific PDE4 inhibition (Mori et al., 2010; Paes et al., 2021; Robichaud et al., 2002). Hence, even more specific targeting, i.e. of individual PDE4D isoforms, may be needed for an efficacious and clinically safe treatment strategy. Previously, we reported that PDE4D expression is isoform-specifically altered in post-mortem brains of AD patients and that this expression correlates with the degree of pathology and cognitive decline (Paes et al., 2020a). Specific PDE4D isoforms may therefore contribute more to AD-associated memory deficits and thus be more promising pharmacological targets. Strikingly, the different isoforms encoded by the *PDE4D* gene localize to different intracellular compartments and regulate distinct cAMP signaling domains (Baillie, 2009; Baillie et al., 2019; Houslay, 2010; Paes et al., 2021). Neuronal plasticity, which is modulated by cAMP and involves dynamic neurite growth, is crucial for proper memory consolidation (Batty et al., 2017; Mingorance-Le Meur and O'Connor, 2009). In AD, neuronal plasticity is found to be heavily impaired (Mesulam, 1999). Non-selective PDE4 inhibition promotes neuronal plasticity and can restore A $\beta$ -induced plasticity impairments (Shrestha et al., 2006). Moreover, genetic ablation of PDE4D appears to specifically increase the number of neurites *in vivo* (Shelly et al., 2010). These findings indicate that PDE4D regulates cAMP signaling domains involved in neuronal plasticity. Therefore, it is crucial to understand which specific PDE4D isoforms control these processes to identify safe pharmacological targets for memory enhancement in AD.

Here, we investigated how PDE4D isoform expression levels and downstream cAMP-PKA-CREB signaling are affected in transgenic AD mouse brains and in A $\beta$ -exposed mouse hippocampal neurons. Furthermore, by means of pharmacological inhibition and CRISPR-Cas9-mediated knockdown, we determined which individual PDE4D isoforms regulate neuronal plasticity *in vitro* and whether ablation of specific isoforms can convey resilience against A $\beta$  toxicity.

## **METHODS**

### **Animals and behavioral testing**

All experimental procedures were approved by the local ethical committee of Hasselt University for animal experiments and met governmental guidelines. Eighteen female wild-type (C57bl/6 OlaHsd) and twenty-two female transgenic Alzheimer mice (APP<sup>swe</sup>/PS1<sup>dE9</sup>) were used. Mice were genotyped by PCR analysis of ear biopsies. At the age of 7 months, animals were housed individually in standard cages on sawdust bedding in an air-conditioned room (about 20°C). They were kept under a reversed 12/12 h light/dark cycle (lights on from 20.00 to 08.00) and had free access to food and water. Mice were housed and tested in the same room. A radio, which was playing softly, provided background noise in the room. The object location task and Y-maze spontaneous alterations were performed as previously described (Sierksma et al., 2014; Sierksma et al., 2013).

### **Brain and stomach tissue processing**

Mice were sacrificed by intracardial perfusion using PBS and heparin solution for 10 minutes under deep pentobarbital anesthesia (200 mg/kg). Stomachs (n=8 of wild-type mice) and brains (n=14/genotype) were removed and hippocampus and prefrontal cortex were dissected, snap-frozen in liquid nitrogen and stored at -80 °C until further processing.

### **Cell culture**

Neuro2a (N2a) mouse neuroblastoma (CCL-131™, ATCC, Wesel, Germany) and HT22 mouse hippocampal cell lines (kind gift from Dr. Amalia Dolga, Rijksuniversiteit Groningen) (Davis and Maher, 1994; Morimoto and Koshland, 1990) were cultured in DMEM/F-12 supplemented with GlutaMAX™ (Gibco), 10% fetal bovine serum and penicillin/streptomycin. For treatment with GEBR32a (European patent EP2907806A1) and/or amyloid- $\beta_{1-42}$  ( $A\beta_{1-42}$ ; AS-24224, Eurogentec),

compounds were dissolved in 100% dimethyl sulfoxide (DMSO) and diluted into culture medium at a final concentration of 0.1% DMSO.

### **Brain PDE4 activity**

PDE activity was measured using a radioactive cAMP hydrolysis assay as described previously (Marchmont and Houslay, 1980). Specific PDE4 activity was determined as pmol cAMP hydrolyzed/min/mg protein as the activity that was ablated by inclusion of 10  $\mu$ M rolipram (PDE4 inhibitor). Background readings were determined in control tubes where no protein was added. Background values were subtracted before values were normalized to pmol cAMP hydrolyzed/min/mg protein.

### **Quantitative PCR**

RNA was extracted from hippocampal and prefrontal cortical tissue, HT22 cells (treated with 0.1% DMSO or 1  $\mu$ M A $\beta$ <sub>1-42</sub> for 24h) and mouse stomach tissue using standard TRIzol-chloroform procedure (TRIzol, Invitrogen). Subsequently, complementary DNA (cDNA) was synthesized using qScript™ cDNA SuperMix (QuantaBio) according to the manufacturer's protocol. Quantitative PCR (qPCR) was performed using the primers listed in Table 1 in combination with SensiMix 2X (Bioline) according to the manufacturer's protocol. All qPCR reactions were performed in duplicate using 12.5 ng sample cDNA and the LightCycler 480 (Roche). The reaction protocol consisted of a polymerase activation cycle (95 °C for 10 min), 40 amplification cycles (95°C for 15 s, primer-specific annealing temperature ( $T_a$ ; Table 1) for 15 s and 72°C for 15 s), followed by a melting curve cycle (95°C for 5 s and 70°C for 1 min) and cooling cycle (40°C for 30 s). Raw expression data from the LightCycler 480 were analyzed using LinRegPCR to determine logarithmic fluorescence values at cycle zero (Log<sub>10</sub> start fluorescence) (Ruijter et al., 2009). qPCR reactions that did not show fluorescent signal amplification were excluded from further analysis. Logarithmic fluorescence values were normalized against the

average expression of the reference genes that showed most stable expression based on geNorm criteria (i.e. *Ywhaz* and *Ppia* for hippocampus; *Ywhaz* and *18s* for frontal cortex; *Ppia* for HT22; *Gapdh* and *Ppia* for stomach) (Vandesompele et al., 2002). Normalized data were used for statistical analysis.

### Genetic knockdown of PDE4D isoforms

Single guide RNAs (gRNA) targeted against murine *Pde4d* isoform-specific DNA sequences (Table 2) were designed with the Zhang-lab online webtool (<http://crispr.mit.edu>) and cloned as annealed oligos into the pSpCas9(BB)-2A-GFP (PX458) vector (kindly provided by Feng Zhang; Addgene plasmid #48138 ; <http://n2t.net/addgene:48138>; RRID:Addgene\_48138) as described previously (Ran et al., 2013). Briefly, purchased *E. coli* (Stabl) expressing the PX458 vectors were cultured in LB with 100 ng/μl ampicillin. PX458 vectors were isolated and purified using a NucleoSpin Plasmid EasyPure kit (Macherey-Nagel). Purified DNA was quantified using a NanoDrop™ 2000 Spectrophotometer (ThermoFisher) and used for restriction using the FastDigest Bpil (IIs class) restriction enzyme (FD1014, Thermo Scientific). Digestion was validated by means of agarose gel electrophoresis and cut vector was excised from the agarose gel using a NucleoSpin Gel and PCR Clean-up kit (Macherey-Nagel). Annealed gRNA oligos were ligated into the restricted and

purified PX458 vector using T4 DNA Ligase (EL0014, Thermo Scientific). Correct incorporation of the gRNA and vector integrity were validated by means of Sanger sequencing and restriction analysis. One Shot Stbl3 chemically competent *E. coli* (Invitrogen) were transformed with the ligated vectors by means of heatshock and then cultured in ampicillin-containing LB agar plates for subsequent colony selection. Colonies were picked and cultured, followed by vector isolation and purification using a NucleoBond Xtra Midi EF kit (Macherey-Nagel, Düren, Germany). Purified PX458 containing the gRNAs complementary to PDE4D isoform-specific sequences were used to transfect HT22 cells using NeuroMag reagent (Oz Biosciences). Unrestricted vector with a short scrambled gRNA sequence was used as a negative control vector. The expected frameshift frequencies upon CRISPR-induced DNA cuts (Table 2) were calculated using the inDelphi machine-learning algorithm established by David K. Gifford, Jonathan Yee-Ting Hsu and Max Walt Shen (Shen et al., 2018).

**Table 2.** Oligonucleotide sequences to be annealed and ligated in the PX458 vector as gRNA against PDE4D isoforms.

Following the functional experiments, a selection of sgRNAs were validated for their effective targeting of the predicted site. DNA from HT22 cells was isolated with the DNeasy Blood & Tissue kit (Qiagen) according to manufacturer's

instructions. A cell-free cleavage assay was performed using the Guide-It sgRNA In Vitro Transcription and Screening System (Takara Bio) according to manufacturer's instructions. Primer sequences and results are described in Supplementary Table 1, Supplementary Table 2, and Supplementary Figure 1.

### **Western blotting**

Mouse hippocampal (HIP) and prefrontal cortex (PFC) tissues were homogenised and reconstituted in lysis buffer (25 mM Tris-HCl, 150 mM NaCl, 0.5% sodium deoxycholate, 1% NP-40, 1 mM DTT, 0.1% SDS; pH 7.5), supplemented with complete protease inhibitor and PhosSTOP phosphatase inhibitor (Roche). Protein extracts were diluted in SDS sample buffer (10% SDS, 300mM Tris-HCl, 0.05% bromothymol blue, 10%  $\beta$ -mercaptoethanol) and combined to create three replicates of 12.5  $\mu$ g total protein per condition per tissue type. Cell extracts were resolved in 4-12% gradient SDS-PAGE and transferred onto nitrocellulose membranes (Bio-Rad Laboratories). Membranes were blocked in TBS-based Intercept Blocking Buffer (Li-Cor) for 1h at room temperature, followed by incubation in Total Protein stain (Li-Cor, 926-11011) to confirm appropriate transfer. Membranes were then destained as per manufacturer's instructions (Li-Cor) and incubated overnight in rabbit anti-phosphoCREB (Ser133) (1:1000, #9191, Cell Signaling Technology), rabbit anti-CREB (1:1000, #9192, Cell Signaling Technology), rabbit anti-PKA phospho-substrate (1:1000, # 9621, Cell Signaling Technology), rabbit anti-Pan PDE4D (1:3000, Abcam, ab171749) and mouse anti-GAPDH (1:3000, Abcam, ab8245) at 4°C, and subsequently incubated with donkey anti-rabbit IRDye 800nm (1:10.000, Li-Cor, 926-33213) and donkey anti-mouse IRDye 700nm (1:10.000, Li-Cor, 926-68072) for 1h at room temperature.

For western blots of N2a cell extracts, cells were lysed using 3T3 lysis buffer (25 mM HEPES, 25 mM EDTA, 50 mM NaCl, 50 mM NAF, 30 mM sodium pyrophosphate, 10% glycerol, 1% Triton-X; pH 7.5) supplemented with protease inhibitor mix and PhosSTOP phosphatase inhibitor (Roche). Cell extracts (12.5  $\mu$ g

total protein) were resolved in 10% SDS polyacrylamide gel electrophoresis and then transferred onto nitrocellulose membranes (Bio-Rad Laboratories). The membranes were blocked (50% Odyssey blocking buffer in PBS; Li-Cor, Lincoln, NE) for 1h at room temperature, followed by overnight incubation rabbit anti-phosphoCREB (Ser133) (1:1000, #9198, Cell Signaling Technology), mouse anti-CREB (1:1000, #9104, Cell Signaling Technology) and mouse anti-GAPDH (1:1,000,000, #10R-G109A; Fitzgerald Industries, Acton, MA) at 4°C. Membranes were subsequently incubated with goat anti-rabbit IRDye 800 (1:10.000, Li-Cor, 926-32211) and donkey anti-mouse IRDye 680 (1:10.000, Li-Cor, 926-68072) for 1h at room temperature. All immunoblots were visualized using the Odyssey CLx scanner, and protein bands were quantified using ImageJ by means of densitometry (Schneider et al., 2012).

### **Neuronal morphology assessment**

To assess neuronal morphology of N2a and HT22 cells, cells were seeded in 24- or 48-wells plates to be treated with GEBR32a and/or A $\beta$ <sub>1-42</sub> or to be transfected. N2a cells were treated with DMSO or 0.1-1.0  $\mu$ M GEBR32a for 48h (n=6/condition). HT22 cells were incubated with DMSO (n=12/condition) or 0.01-1.0  $\mu$ M GEBR32a (n=6/condition). In another set of experiments, HT22 cells were treated with 0.5-1.0  $\mu$ M A $\beta$ <sub>1-42</sub> alone and GEBR32a (1  $\mu$ M) and A $\beta$ <sub>1-42</sub> (1  $\mu$ M) and incubated for 24h (n=6/condition). For transfection experiments, HT22 cells were cultivated for 48h upon transfection or exposed to 1  $\mu$ M A $\beta$ <sub>1-42</sub> for 24h, one day post-transfection (n=9-12/condition). To visualize and quantify neuronal morphology, the Neurite Outgrowth Staining Kit (A15001, Invitrogen) was used to fix and membrane-stain the cells according to the manufacturer's protocol. Pictures (20x magnification) were taken with an Olympus IX81 inverted microscope connected to an ORCA-fusion digital CMOS camera (C14440-20UP, Hamamatsu) using the MicroManager open source software (Edelstein et al., 2010; Edelstein et al., 2014). Per well, three images were captured and used for neurite outgrowth analysis by the NeuronJ plugin for ImageJ (Meijering et al., 2004; Schneider et al., 2012). Average neurite length per

condition was normalized against the control conditions (i.e. DMSO-treated or control-transfected cells).

### **cAMP determination in cultured cells**

To evaluate the effect of PDE4D-inhibition by GEBR32a on global intracellular cAMP levels, N2a and HT22 cells were seeded in 12 well plates at  $10^6$  cells per well. Cells were treated with DMSO or GEBR32a 0.01-3  $\mu\text{M}$  ( $n \geq 4$ /condition) and 1  $\mu\text{M}$  of the adenylyl cyclase activator forskolin (MedChemExpress, HY-15371) for 1h and subsequently lysated in 0.1M HCl. Concentrations of cAMP were measured using the Cyclic AMP ELISA Kit (Cayman Chemical Company, 581001) according to manufacturer's instructions. Results are depicted as fold change over DMSO control.

### **Immunocytochemistry**

To investigate PDE4D protein localization, HT22 cells were seeded on 12mm glass coverslips (VWR, 631-1577) coated with 100  $\mu\text{g}/\text{mL}$  Poly-L-Ornithine (Sigma, P4957) and 1  $\mu\text{g}/\text{mL}$  laminin (Sigma, L2020) and grown for 24h. After fixation in 4% paraformaldehyde, cells were permeabilized using 0.1% TritonX-100. After blocking with 10% BSA for 1h, cells were incubated with rabbit anti-PDE4D (1:250; ab14613, Abcam) overnight at 4°C. Then, cells were incubated with goat anti-rabbit Alexa647 (1:250; Invitrogen) for 1h at room temperature. Finally, nuclei were counterstained with Hoechst (1:500; Sigma).

For immunocytochemistry following transfection experiments in HT22, the same protocol was used except for the antibodies used. Mouse anti-FLAG primary antibodies (1:1000; M2 clone, Sigma-Aldrich) and donkey anti-mouse Alexa488-conjugated secondary antibody (1:250; Invitrogen) were used to determine which cells were successfully transfected and expressed the FLAG-encoding PX458 plasmid. PDE4D localization was imaged after mounting the coverslips on microscope glasses

using a disc spinning unit (DSU) microscope (Olympus). Morphology assessment of transfected, FLAG-positive HT22 cells was performed as described above.

### **Gene ontology (GO) term enrichment analysis**

Determining the involvement of PDE4D in specific biological processes was approached by examining whether known PDE4D interaction proteins are enriched in these processes. The list of known PDE4D interactors was retrieved from BioGRID (<https://thebiogrid.org/>) (Stark et al., 2006) and used for gene ontology (GO) term enrichment analysis using ToppGene Suite with default settings (<https://toppgene.cchmc.org/>) (Chen et al., 2009). The complete GO analysis output of significantly enriched Biological Process GO terms can be found in Table 3.

### **Statistical analysis**

For the OLT and Y-maze behavioral tasks, memory performance of WT and APP<sup>swe</sup>/PS1<sup>dE9</sup> was assessed statistically by performing two-tailed paired t-tests between genotypes and comparing performance of each genotype against chance performance (i.e. 0 for OLT and 50% for Y-maze). Likewise, normalized qPCR, PDE4 activity, and WB values were used to compare expression/activity differences between genotypes by means of two-tailed t-tests. For *in vitro* studies on neurite length, CREB phosphorylation, and cAMP concentration, one-way ANOVAs were performed with Dunnett's post-hoc t-tests using the DMSO condition as control. Differences in PDE4D isoform mRNA expression between DMSO- and A $\beta$ -treated HT22 cells were investigated by means of two-tailed t-tests. The effect of genetic knockdown of PDE4D isoforms on neuronal morphology was analyzed by means of one-way ANOVA of normalized neurite lengths followed by Dunnett's post-hoc t-tests. The effect of genetic knockdown of PDE4D isoforms in combination with A $\beta$  exposure was compared to control-transfected conditions with and without exposure to A $\beta$  by means of one-way ANOVA followed by Dunnett's post-hoc t-tests.

## RESULTS

### Impaired spatial memory and altered PDE4D-mediated cAMP-PKA-CREB signaling in female APP/PS1 mice

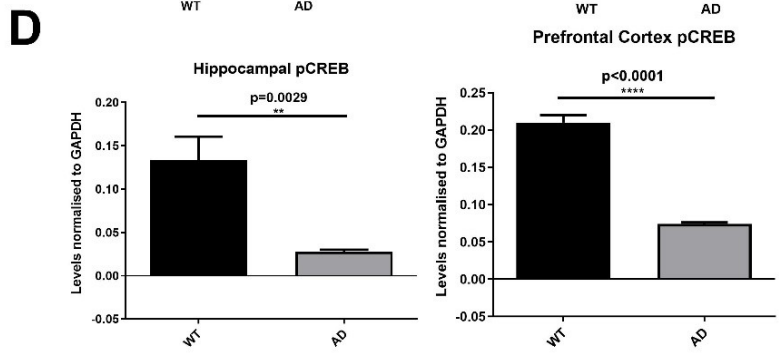

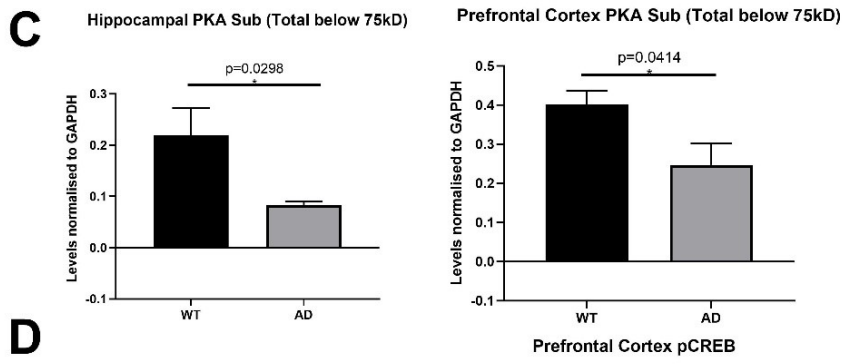

Spatial memory assessment in the OLT and Y-maze spontaneous alterations task demonstrated that APP/PS1 mice were cognitively impaired compared to WT mice. More specifically, in the OLT, both genotypes showed intact memory performance using a 1-hour inter-trial interval (Fig 1A; ###:  $P < 0.001$  two-tailed t-test against 0). Using a 4-hour interval, WT mice showed intact spatial memory, whilst APP/PS1 did not (###:  $P < 0.001$  paired two-tailed t-test against 0). In addition, APP/PS1 mice performed significantly worse than WT mice (Fig 1A; \*\*\*:  $P < 0.001$  two-tailed t-test). Similarly, whilst both genotypes performed significantly better than chance level in the Y-maze spontaneous alterations task (Fig 1B; ##:  $P < 0.01$ , ###:  $P < 0.001$ , paired two-tailed t-test against 50%), APP/PS1 mice performed worse than WT mice (\*:  $P < 0.05$ , two-tailed t-test).

After observing the memory deficits in APP/PS1 mice, hippocampal and frontal cortical tissue of these animals was used for biochemical assessments to investigate potentially associated alterations in PDE4D-mediated cAMP-PKA-CREB signaling. PDE4D mRNA expression of specific isoforms was found to be higher in APP/PS1 in both brain regions. In the hippocampus, PDE4D1, -D3, and -D8 expression was 1.6 to 4.6-fold higher, whilst PDE4D3 and -D5 were 2.1 to 3.7-fold upregulated in the frontal cortex (Fig 1C-D; \*:  $P < 0.05$ , two-tailed t-test). At the protein level, general PDE4D expression showed a non-significant increase in the APP/PS1 hippocampus, which was not observed in the frontal cortex (Fig 2A). PDE4 activity was found to be 3-fold higher in the hippocampus, but not in the frontal cortex, of APP/PS1 compared to WT mice (Fig 2B; \*\*\*:  $P < 0.001$ , two-tailed t-test). Moreover, assessment of protein expression of phosphorylated PKA substrates and phosphorylated CREB were found to be significantly lower in the hippocampus and

frontal cortex of APP/PS1 mice (Fig 2C-D; \*:  $P < 0.05$ , \*\*:  $P < 0.01$ ; \*\*\*:  $P < 0.001$ , \*\*\*\*:  $P < 0.0001$ ).

**Figure 1. Changes in memory performance and PDE4D-mediated cAMP-PKA-CREB signaling in female APP/PS1 mice compared to wild-type mice.** A) Spatial memory performance of WT and APP/PS1 mice in the object location task. Using a 4-hour inter-trial interval revealed impaired memory performance in APP/PS1, but not wild-type (WT) mice (\*\*\*:  $P < 0.001$ , two-tailed t-test comparing genotypes; ###:  $P < 0.001$ , paired two-tailed t-test against 0;  $n = 18-22$ /genotype). B) Spatial memory performance in the Y-maze spontaneous alternations task. Intact memory, i.e. higher than chance (50%), was found for both genotypes and significantly higher memory performance in WT versus APP/PS1 mice (\*:  $P < 0.05$ , two-tailed t-test; #:  $P < 0.01$ , ###:  $P < 0.001$ , paired two-tailed t-test against 50%;  $n = 18-22$ /genotype). C-D) PDE4D isoform mRNA expression in hippocampus and frontal cortex of WT and APP/PS1 mice ( $n = 7-8$ /genotype). Significantly increased expression of specific isoforms was measured in APP/PS1 versus WT mice (\*:  $P < 0.05$ , two-tailed t-test).

**Figure 2. PDE4D protein expression, PDE4 activity and cAMP-PKA-CREB signaling changes in hippocampus and cortex of WT and APP/PS1 mice.** A) PDE4D protein expression in hippocampus and cortex of WT and APP/PS1 mice (n=3/genotype). B) Specific PDE4 activity in homogenates of PFC and hippocampal tissue excised from APP/PS1 and WT mice normalized for amount of protein (n=3/genotype). C) Densitometric quantification of western blots measuring phospho-PKA substrates normalized to GAPDH in WT versus APP/PS1 mice (n=6/genotype). D) Densitometric quantification of western blots measuring phosphorylated CREB normalized to GAPDH in WT versus APP/PS1 mice (n=6/genotype, \*:  $P < 0.05$ , \*\*:  $P < 0.01$ , \*\*\*\*:  $P < 0.0001$ , two-tailed t-test). Data are presented as mean + SEM. Western blot scans are provided in the Supplementary Material.

### **Pharmacological PDE4D inhibition increases CREB phosphorylation and neurite length in N2a cells**

To validate the involvement of PDE4D in cAMP-PKA-CREB signaling and neuronal plasticity, N2a cells were treated with the PDE4D-selective inhibitor GEBR32a. After 1h incubation with GEBR32a (0.03-1.0  $\mu\text{M}$ ), phosphorylated CREB (pCREB) and total CREB levels were measured by means of western blotting. One-way ANOVA revealed significant differences in normalized pCREB/CREB ratio between conditions ( $F(5,30) = 17.83$ ,  $P < 0.0001$ ). Compared to the DMSO condition, significant increases in pCREB/CREB ratio were found for 0.3 and 1.0  $\mu\text{M}$  GEBR32a (\*:  $P < 0.05$ , \*\*:  $P < 0.05$ , Dunnett's post-hoc t-tests; Fig 3A). Moreover, upon 1h treatment with 3  $\mu\text{M}$  GEBR32a, cAMP levels in N2a cells can increase up to 5-fold compared to the DMSO control (Dunnett's post-hoc t-tests; Supplementary Fig 1).

Similarly, N2a cells were treated with GEBR32a to assess the effects of PDE4D inhibition on neuronal morphology by measuring neurite lengths. After 48h incubation with GEBR32a (0.1-1.0  $\mu\text{M}$ ) neurite lengths were measured. One-way ANOVA revealed significant differences in the average neurite length between conditions ( $F(3,20) = 6.886$ ,  $P < 0.01$ ). Compared to the DMSO condition, significant increases in average neurite length were found for 0.3 and 1.0  $\mu\text{M}$  GEBR32a (\*\*:  $P < 0.01$ , Dunnett's post-hoc t-tests; Fig 3B-C). These findings indicate that, in the N2a

cell line, CREB phosphorylation and neurite elongation are stimulated by GEBR32a-induced PDE4D inhibition at 1h and 48h, respectively.

**Figure 3. PDE4D inhibition dose-dependently increased CREB phosphorylation and neurite length in N2a cells.** A) Phosphorylated CREB (pCREB) to total CREB ratios in N2a cells upon treatment with 0.03-1.0 μM GEBR32a for 1h (Dunnett's post-hoc: \* $P < 0.05$ , \*\*\* $P < 0.001$ ;  $n = 6$ /condition). Representative blot scans are shown under the graph. B) Average neurite after incubation with 0.1-1.0 μM GEBR32a for 48h in N2a cells (Dunnett's post-hoc: \*\* $P < 0.01$ ;  $n = 6$ /condition). C) Exemplary microscope images indicating N2a neurites in the DMSO (left) and 1.0 μM GEBR32a (right) conditions that were visualized for subsequent tracing. Data is presented as mean + SEM.

## Pharmacological PDE4D inhibition induces longer neurites in mouse hippocampal cells

Next, complementing the findings in the mouse neuroblastoma N2a cells, we sought to identify the role of PDE4D in regulating neuronal morphology in the mouse hippocampal HT22 cell line to better approximate the *in vivo* context in which we found changes in hippocampal PDE4D-mediated cAMP-PKA-CREB signaling (Fig 1 and 2). Specifically, HT22 cells were incubated with 0.01-1.0  $\mu\text{M}$  GEBR32a for 48h to assess the effects of pharmacological PDE4D inhibition on neuronal morphology. One-way ANOVA revealed significant differences in the average neurite length between conditions ( $F(5,36) = 14.60$ ,  $P < 0.001$ ). Compared to control samples, significant increases in average neurite length were found in cells treated with 0.03-1.0  $\mu\text{M}$  GEBR32a (Fig 4A-B; \*\*\*: $P < 0.001$ , \*\*\*\*: $P < 0.0001$ , Dunnett's post-hoc t-tests). Incubation with 3  $\mu\text{M}$  GEBR32a increased cAMP levels 5-fold (Supplementary Fig 2).

As inhibition of PDE4D significantly increased neurite length, we investigated whether PDE4D is localized in or near neurite growth cones to locally regulate cAMP signaling. Based on immunocytochemistry, it was found that PDE4D is expressed in the neurite growth cones of HT22 cells (Fig 4C). Additional support for a role of PDE4D in regulating neuronal morphology was found by investigating the shared biological processes of known PDE4D interaction proteins. The list of known PDE4D interaction proteins was retrieved from BioGRID (Stark et al., 2006) and subjected to gene ontology (GO) enrichment analysis using ToppGene Suite (Chen et al., 2009). PDE4D interacting proteins were found to be significantly enriched in biological processes regulating (neuronal) morphology (Fig 4D). More specifically, 'neuron project development' (GO:0031175) was found to be most significantly enriched. Through interaction with the proteins enriched in these processes, PDE4D is likely to be optimally localized to regulate neuronal morphology. The complete GO analysis including interaction proteins per biological process can be found in Supplementary Table 3.

C) Representative HT22 immunofluorescence image showing the predominant localization of PDE4D in neurites and their growth cones. D) Gene ontology (GO) term enrichment analysis of biological processes of PDE4D interaction proteins (retrieved from BioGRID (Stark et al., 2006)) showing enrichment for processes related to (neuronal) morphology regulation (in bold). Top twenty terms are shown, the entire list is provided in Supplementary Table 3. Data is presented as mean + SEM.

**Pharmacological PDE4D inhibition protects against  $\text{A}\beta_{1-42}$ -induced reductions in neurite length**

Since APP/PS1 mice showed impaired spatial memory performance and altered cAMP-PKA-CREB signaling as a result of excessive  $\text{A}\beta$  production, we subsequently examined whether  $\text{A}\beta_{1-42}$  exposure negatively impacts neurite growth in HT22 cells and whether PDE4D inhibition can protect against these effects. HT22 cells were incubated for 24h with 0.5-1.0  $\mu\text{M}$   $\text{A}\beta_{1-42}$  or a combination of  $\text{A}\beta_{1-42}$  and GEBR32a (both 1  $\mu\text{M}$ ). One-way ANOVA revealed significant differences in the average neurite length between conditions ( $F(3,20) = 6.932$ ,  $P < 0.01$ ). Compared to the DMSO condition, a significantly decreased average neurite length was found for 1.0  $\mu\text{M}$   $\text{A}\beta_{1-42}$  (Fig 5A ; \*: $P < 0.05$ , Dunnett's post-hoc t-tests). Combined incubation with  $\text{A}\beta_{1-42}$  and GEBR32a was able to prevent this  $\text{A}\beta_{1-42}$ -induced neurite length reduction (Fig 5A; ##: $P < 0.01$ , two-tailed t-test). PDE4D expression measurement indicated that, concurrent with reducing the HT22 average neurite length, 1  $\mu\text{M}$   $\text{A}\beta_{1-42}$  increases mRNA expression of the specific isoforms PDE4D3 and -D5 (Fig 5B; \*: $P < 0.05$ , \*\*: $P < 0.01$ , two-tailed t-test). It should be noted that PDE4D4 and PDE4D8 mRNA could not be detected in HT22 cells.

**Figure 5. Aβ<sub>1-42</sub> exposure reduced the average neurite length in HT22 cells and increased isoform-specific PDE4D expression.** A) Average neurite length after incubation of HT22 cells with 0.5-1.0 μM Aβ<sub>1-42</sub> or GEBR32a and Aβ<sub>1-42</sub> (both 1 μM) for 24h (Dunnett's post-hoc: \*P<0.05; two-tailed t-test: ##:P<0.01; n=6/condition). B) PDE4D isoform mRNA expression after 1 μM Aβ<sub>1-42</sub> exposure for 24h in HT22 (\*:P<0.05, \*\*:P<0.01, two-tailed t-test; n=6/condition). Data is presented as mean + SEM.

**Figure 6. Genetic knockdown of specific PDE4D isoforms caused increased HT22 neurite length and protected against  $A\beta_{1-42}$ -induced neurite length reduction.** HT22 cells were transfected with CRISPR-Cas9 vectors to genetically knock down specific PDE4D isoforms. A) Average neurite lengths upon PDE4D isoform knockdown 48h after transfection (\*\*: $P < 0.01$ , \*\*\*: $P < 0.001$ , \*\*\*\*: $P < 0.0001$ , Dunnett's post-hoc t-tests;  $n = 9-12$ /condition). B) Average neurite lengths upon PDE4D isoform knockdown 48h after transfection with  $1 \mu M A\beta_{1-42}$  exposure during the last 24h (\*\*\*\*: $P < 0.0001$ , Dunnett's post-hoc t-tests compared to control with  $A\beta_{1-42}$  exposure;  $n = 9$ /condition). Comparisons against control transfection without  $A\beta_{1-42}$  exposure with higher average neurite lengths are shown by hashes (##:  $P < 0.01$ , Dunnett's post-hoc t-tests). For clarity, significantly lower neurite lengths than control without  $A\beta_{1-42}$  (i.e. CTRL +  $A\beta_{1-42}$ , D1, D4, D6, and D8 based on Dunnett's post-hoc t-tests) are not indicated in the graph. Data is presented as mean + SEM.

## Neurite growth is regulated by long PDE4D isoforms both in absence and presence of A $\beta$ <sub>1-42</sub>

PDE4D isoforms seem to be differentially expressed upon A $\beta$ <sub>1-42</sub> exposure both *in vivo* (Fig 1C-D) and *in vitro* (Fig 5B), and isoforms are known to localize to distinct cellular compartments to regulate specific processes (Houslay, 2010). As non-specific inhibition of all PDE4D isoforms may cause severe adverse effects, we investigated whether specific PDE4D isoforms regulate neurite growth in HT22 cells and could serve as a more specific therapeutic target for AD treatment. Individual PDE4D isoforms were genetically knocked down in HT22 cells by transfection with CRISPR-Cas9 vectors, after which average neurite length was measured. 48h after transfection, one-way ANOVA revealed significant differences in the average neurite length between conditions ( $F(8,75) = 12.36, P < 0.0001$ ). Compared to the control condition, 1.36 to 1.59-fold increased average neurite lengths were found for knockdown of PDE4D3, -D5, -D7, and -D9 (Fig 6A; \*\*: $P < 0.01$ , \*\*\*: $P < 0.001$ , \*\*\*\*: $P < 0.0001$ , Dunnett's post-hoc t-tests).

Next, it was examined whether PDE4D isoform knockdown could prevent A $\beta$ <sub>1-42</sub>-induced reductions in average neurite length. To this purpose, PDE4D isoforms were knocked down and cells were exposed to 1  $\mu$ M A $\beta$ <sub>1-42</sub> for 24h one day post-transfection after which average neurite lengths were measured. One-way ANOVA revealed significant differences in the average neurite length between conditions ( $F(8,68) = 36.34, P < 0.0001$ ). In the presence of A $\beta$ <sub>1-42</sub>, knockdown of PDE4D3, -D5, -D7, and -D9 increased average neurite length by 1.38 to 1.46-fold increased average neurite lengths were found for when compared to the control condition with A $\beta$ <sub>1-42</sub> (\*\*\*\*: $P < 0.0001$ , Dunnett's post-hoc t-tests; Fig 6B). Moreover, in the absence of A $\beta$ <sub>1-42</sub>, average neurite length upon control transfection was significantly higher than upon control transfection with A $\beta$ <sub>1-42</sub> (\*\*\*\*: $P < 0.0001$ , Dunnett's post-hoc t-tests; Fig 6B). Compared to the control condition without A $\beta$ <sub>1-42</sub>, PDE4D3 and -D9 knockdown countered the effect of A $\beta$ <sub>1-42</sub> and was associated

with significantly increased average neurite length (##:P<0.01, Dunnett's post-hoc t-tests, Fig 6B). Knockdown of PDE4D1, -D4, -D6, and -D8 with exposure to A $\beta$ <sub>1-42</sub> led to significantly lower average neurite lengths compared to the control condition without A $\beta$ <sub>1-42</sub> exposure (P<0.0001, Dunnett's post-hoc t-test, not shown in the graph).

### **Not all neurite growth-controlling PDE4D isoforms are expressed in the mouse stomach**

Upon determining PDE4D isoforms mediating neurite growth processes, PDE4D isoform expression was measured in the mouse stomach to assess which PDE4D isoforms would likely mediate gastrointestinal side effects in the stomach upon PDE4(D) inhibition. As shown in Figure 7, the expression profile of PDE4D in the mouse stomach differs from the expression in the mouse hippocampus (Fig 1C), prefrontal cortex (Fig 1D), and HT22 cells (Fig 5B). Interestingly, of the neurite growth-controlling PDE4D isoforms (i.e. PDE4D3, -D5, -D7, and -D9), PDE4D3 and PDE4D5 show a similarly high level of expression in the mouse stomach, whilst PDE4D7 and PDE4D9 are 6.6-fold and >1700-fold lower expressed than PDE4D3 and PDE4D5.

**Figure 7. Isoform-specific PDE4D expression in the stomach of wild-type mice.** mRNA expression of PDE4D isoforms was measured in stomach tissue of wild-type mice by means of qPCR (n=8) indicating highest expression of PDE4D3 and PDE4D5.

## DISCUSSION

cAMP-PKA-CREB signaling has been well-established as a pathway that is crucial for synaptic plasticity and memory consolidation (Kandel, 2012). Moreover, impaired memory consolidation and cognitive deficits in AD have been associated with deficient cAMP-PKA-CREB signaling (Saura and Valero, 2011). Inhibition of the cAMP-degrading PDE4D enzymes has been found to restore memory functioning in transgenic AD mice (Cui et al., 2019; Sierksma et al., 2014). Despite this therapeutic potential, non-specific PDE4D inhibition has been associated with severe adverse effects (e.g. nausea and vomiting), which has hampered clinical progression of PDE4(D) inhibitors (Blokland et al., 2019a; Paes et al., 2021). Remarkably, PDE4D enzymes comprise multiple protein isoforms that show tissue- and cell type-specific expression and regulate distinct intracellular processes (Baillie et al., 2019; Houslay, 2010; Paes et al., 2021). Hence, treatment efficacy may be enhanced or maintained, while side effects are reduced, by specifically targeting those PDE4D isoforms that are involved in synaptic plasticity. Therefore, we investigated whether PDE4D isoforms are differentially expressed in transgenic AD mice and whether specific PDE4D isoforms control neurite growth as a measure of plasticity. Additionally, we examined whether PDE4D inhibition or individual PDE4D isoform knockdown could protect against A $\beta$ -induced toxicity.

Cognitive phenotyping revealed spatial memory deficits in female APP/PS1 mice at 7 months of age. These findings replicate a prior study using the same genotypes and behavioral tasks (Sierksma et al., 2014). In our follow-up biochemical assessment, it was demonstrated that CREB phosphorylation was reduced in the hippocampus and frontal cortex of APP/PS1 mice. Moreover, we measured mRNA expression increases for PDE4D1, -D3, and -D8 in the hippocampus and for PDE4D3 and -D5 in the frontal cortex of APP/PS1 mice. Recently, we also found the same PDE4D isoforms to show pathology-associated, increased expression in post-mortem human middle temporal gyrus tissue of AD patients (Paes et al., 2020a). In

addition, the observation of increased PDE4D3 mRNA expression in the hippocampus of APP/PS1 mice corresponds to the fact that hippocampal injections of A $\beta$ <sub>1-42</sub> in wild type mice caused elevated PDE4D(3) protein expression (Wang et al., 2016). Here, we also show that PDE4 activity was increased in the hippocampus of APP/PS1 mice, which may be a result of increases in PDE4D3 expression. While we report changes in PDE4D isoform mRNA expression, a non-significant trend of increase was found for PDE4D protein expression in the hippocampus of APP/PS1 mice using an antibody that is not isoform-specific. Multiple isoforms (e.g. PDE4D3 and PDE4D8) would migrate identically on SDS-PAGE and could therefore not be distinguished (Houslay and Conti, 2010). However, our observations are in accordance with previous reports showing increases in hippocampal PDE4D protein expression in transgenic Alzheimer mice and mice exposed to exogenous A $\beta$  (Shi et al., 2021a; Wang et al., 2020). Whether protein levels of specific PDE4D isoforms are upregulated whilst others are unaffected or are downregulated remains to be determined. Most importantly, we conducted the *in vivo* experiment to provide proof-of-concept of the change in PDE4D isoform signature associated with AD-related cognitive decline. Results are similar to the results from our previously reported and abovementioned human AD post-mortem study in which we included both females and males, yielding comparable results (Paes et al., 2020a). Hence, the finding in these female mice provided a step towards the *in vitro* pharmacological inhibition and genetic editing in murine cells.

When examining whether PDE4D inhibition can stimulate cAMP-PKA-CREB signaling, we found that the PDE4D-selective inhibitor GEBR32a significantly increased CREB phosphorylation *in vitro*, which is in accordance with previous studies using PDE4 and PDE4D inhibitors (MacKenzie and Houslay, 2000; Zhang et al., 2017). Moreover, GEBR32a at a concentration of 3  $\mu$ M substantially increased global intracellular cAMP levels in both N2a and HT22 cells. This is in line with the IC<sub>50</sub> of the compound, 2.43  $\mu$ M (Prosdocimi et al., 2018). Furthermore, pharmacological

PDE4D inhibition induced a dose-dependent increase in neurite length in both N2a and HT22 cells. The role of PDE4D in regulating neurite outgrowth was supported by the localization of PDE4D protein in growth cones and the fact that many of known PDE4D-interacting proteins are involved in neuron projection development. As PDE4D was also found to localize to microtubules in neurons of the macaque prefrontal cortex (Datta et al., 2020), there is evidence that PDE4D also regulates neuronal morphology *in vivo*. Pharmacological PDE4D inhibition by GEBR32a enhances neurite outgrowth in N2a and HT22 cells starting at a concentration of 0.03  $\mu\text{M}$ . Considering that global cellular cAMP levels only rise detectably with an ELISA upon 3  $\mu\text{M}$  GEBR32a exposure, lower-dose initiated cAMP changes on a nanoscale level, which would require new high-end detection techniques, are likely sufficient to stimulate neurite growth, providing additional support for PDE4D-associated low-cAMP compartments near growth cones (Bock et al., 2020). Early studies already showed that A $\beta$  exposure can cause neurite degeneration in hippocampal neurons (Ivins et al., 1998). The HT22 mouse hippocampal neuronal cell line we used here also showed reduced neurite length when exposed to 1  $\mu\text{M}$  A $\beta_{1-42}$ , which corresponds to the concentrations that were neurotoxic to HT22 cells in prior studies (Kwon et al., 2010). Pharmacological PDE4D inhibition protected against this A $\beta_{1-42}$ -induced neurite length reduction.

However, as PDE4D inhibition has been associated with severe adverse effects, which may be due to central and/or peripheral actions, targeting of specific PDE4D isoforms could be therapeutically more effective or enable maintenance of efficacy while improving safety. The PDE4D isoforms (PDE4D1-9) are categorized into long, short, and supershort isoforms, which is based on the inclusion of specific exons and the isoform's eventual protein sequence. The differences in sequence enable for isoform-specific activity modulation by post-translational modifications and for specific intracellular targeting to regulate specific processes (Paes et al., 2021). Hence, we sought to investigate which PDE4D isoforms regulate neurite growth and

convey the protective effect of PDE4D inhibition against A $\beta$ <sub>1-42</sub> exposure. We found that genetic ablation of the long PDE4D isoforms PDE4D3, -D5, -D7, and -D9 increased average neurite length both in absence and in presence of the neurotoxic A $\beta$ <sub>1-42</sub> concentration. Genetic knockdown of the other long isoforms, PDE4D4 and PDE4D8, had no effect on neurite length, which can be explained by the observation that these forms are not expressed in HT22 cells. Since PDE4D8 was expressed more in APP/PS1 hippocampus, this may be linked to expression in non-neuronal cell types (e.g. microglia, astrocytes and/or oligodendrocytes). Remarkably, the short PDE4D1 and supershort PDE4D6 isoform did not affect neurite growth upon genetic knockdown, which implies that neurite outgrowth is specifically regulated by long PDE4D isoforms. The question remains whether these long isoforms regulate the same cellular process or modulate different processes that eventually influence neurite outgrowth. For example, non-specific PDE4 inhibition was found to increase phosphorylation of vasodilator-stimulated phosphoprotein (VASP), a protein that is associated with the cytoskeleton (Fleming et al., 2004), which is likely caused by PKA activation and will promote neurite elongation (Batty et al., 2017; Drees and Gertler, 2008; Mingorance-Le Meur and O'Connor, 2009). Since PDE4D localizes in HT22 neurite growth cones and long PDE4D isoforms appear to regulate neurite outgrowth, these long isoforms may control neuronal morphology by controlling PKA activity, and subsequent phosphorylation of specific targets, in neurite growth cones.

PDE4 subtypes and isoforms are known to localize to specific intracellular compartments (Baillie, 2009; Baillie et al., 2019; Blackman et al., 2011; Houslay, 2010; Terrin et al., 2006; Yougbare et al., 2021). Previous studies may provide insight into how PDE4D3, -D5, -D7, and -D9 influence cAMP signaling in regulating neurite growth. Most notably, PDE4D3 has been reported to bind perinuclear mAKAP, and the PDE4D3/mAKAP complex was found to support survival of and axon growth in neurons (Boczek et al., 2019; Boczek and Kapiloff, 2020). Moreover, PDE4D3 can bind

to the centrosome via AKAP9, thereby regulating cell cycle progression (Terrin et al., 2012). Thus, genetic knockdown of PDE4D3 likely promoted cAMP-PKA signaling in both the perinuclear and centrosomal regions, which may have halted cell cycle progression and promoted neurite growth. In addition, the increased perinuclear cAMP-PKA signaling may have stimulated PKA-mediated CREB phosphorylation, which subsequently could have promoted neuronal plasticity processes (e.g. neurite outgrowth).

By preferentially binding the scaffolding  $\beta$ -arrestin, PDE4D5 can be located in close vicinity of G-protein coupled receptors (GPCRs) to regulate cAMP levels at the site of synthesis near GPCR-stimulated adenylyl cyclase (Baillie, 2009; Baillie et al., 2003; Houslay and Baillie, 2005). Additionally, PDE4D5 is located in the nucleus through interaction with AKAP95 and may therefore also be the specific isoform found in nuclei of cortical neurons in the macaque brain (Clister et al., 2019; Datta et al., 2020). Upon PDE4D5 knockdown, nuclear cAMP-PKA-CREB-mediated signaling and subsequent transcription may be stimulated while also cAMP levels are elevated near GPCRs to induce PKA-mediated phosphorylation of, for example, cytoskeletal proteins to promote neurite outgrowth. Cytoskeletal remodeling and neuronal motility are likely regulated by PDE4D5 species that are complexed with focal adhesion kinase (FAK) through interactions with the scaffold protein RACK1 (Navarro and Rico, 2014; Serrels et al., 2010). Recently, it has been described that GPCR activation can actually recruit PDE4D5 out of the nucleus to allow for nuclear cAMP signaling that promotes memory consolidation (Martinez et al., 2023); PDE4D5 knockdown would have a similar effect.

Similar to PDE4D5, PDE4D7 has been found to locate to the plasma membrane in a prostate cancer cell line and has been linked to regulation of cell proliferation (Henderson et al., 2014). Furthermore, in different cell types, i.e. human arterial endothelial cells, PDE4D7 was found to specifically regulate transcriptional responses to extracellular cues (Burke-Kleinman and Maurice, 2021). Based on these

studies, neuronal PDE4D7 may also locate near the membrane to regulate cAMP-mediated relaying of extracellular signaling to an adaptive transcriptional response. Intriguingly, several single-nucleotide polymorphisms (SNPs) in the PDE4D7 and PDE4D5 promoter regions of the *PDE4D* gene showed significant associations with cognitive performance in humans (Gurney, 2019). Based on our data, it could be suggested that these SNPs, by influencing PDE4D isoform expression, may cause changes in neuronal plasticity (e.g. growing neurites) and thereby cause differences in cognition.

Regarding PDE4D9, a similar intracellular distribution as PDE4D3, i.e. perinuclear and under the plasma membrane, has been reported (Sheppard et al., 2014). In the submembrane compartment, PDE4D9 can bind to and regulate the function of  $\beta_2$ -adrenergic receptors (De Arcangelis et al., 2009). As these receptors regulate neurite outgrowth and are also expressed in HT22 cells, PDE4D9 knockdown may contribute to a stronger or longer sustained signaling downstream of these receptors to facilitate neurite outgrowth (Day et al., 2014; Schmidt et al., 2001). Functionally, PDE4D9 was also found to be phosphorylated by a multitude of kinases to regulate cAMP levels during mitosis (Sheppard et al., 2014) and could, therefore, halt cell cycle progression and induce neurite outgrowth upon knockdown. Moreover, PDE4D9 transcription is repressed by the scaffolding protein disrupted in schizophrenia 1 (DISC1), suggesting that DISC1 loss-of-function can induce increased PDE4D9 expression (Soda et al., 2013). At the protein level, DISC1 directly binds and inhibits PDE4B and PDE4D, providing an additional manner to regulate PDE4D activity (Murdoch et al., 2007). Interestingly, DISC1 loss-of-function mutations have been associated with psychiatric disorders associated with altered neuronal morphology (Tropea et al., 2018). These morphological changes may be partly explained by aberrant cAMP signaling caused by the impaired PDE4D9 transcription regulation and deficient PDE4(D) scaffolding by DISC1.

Thus, the long isoforms PDE4D3, -D5, -D7, and -D9 are well positioned in several cellular compartments to regulate (downstream) GPCR signaling, cAMP-PKA-CREB-mediated transcription, proliferation, cytoskeletal modulation and local PKA-mediated phosphorylation events (Fig 8). By genetic knockdown of separate PDE4D isoforms, local cAMP signaling is enhanced, which translates into a more complex morphology. Moreover, as PDE4D isoform knockdown also provided resilience against  $A\beta_{1-42}$ -induced neurotoxicity, additional cellular mechanisms may be stimulated. The current findings indicate that genetic knockdown of a single PDE4D isoform is sufficient to induce these effects. This may imply that PDE4D isoform knockdown is not directly compensated for by other PDE4D isoforms, at least in the acute setting used here. Based on this rationale, follow-up studies would have to investigate potential synergistic actions of knockdown of multiple PDE4D isoforms. Previous studies have shown that inhibition of different PDE families, that would localize to different intracellular locations, can have synergistic effects (Gulisano et al., 2018; Paes et al., 2020b). Possible additive effects of knockdown of multiple PDE4D isoforms would have to be revealed in such studies. However, pharmacological PDE4D inhibition, which would target multiple PDE4D isoforms, showed effects of similar potency as those observed for single isoform knockdown, making additive effects unlikely. Future studies should determine which (combinations of these) PDE4D isoforms, bound to which interactor proteins, regulate which local signaling module in the context of neuronal plasticity processes like neurite growth. Previously, the use of dominant-negative approaches has proven to be successful in elucidating the localization and function of specific PDE4 isoforms, and may therefore provide a useful tool for follow-up research (McCahill et al., 2005; Ong et al., 2009).

**Figure 8.** Intracellular positioning of specific PDE4D isoforms allows control of cAMP signaling involved in processes regulating neuronal plasticity. PDE4D isoforms can regulate cAMP signaling at the site of synthesis (PDE4D9 near  $\beta$ -adrenergic receptors, PDE4D5 binding GPCR-recruited  $\beta$ -arrestin, and submembranous PDE4D7). Upon synthesis by transmembrane (tmAC) or soluble (sAC) adenylyl cyclases, cAMP signals can be relayed to centrosomal areas where PDE4D3 is sequestered by AKAP9 or to cytoskeletal areas where PDE4D5 is complexed to FAK by RACK1. This localization allows for PDE4D-mediated control of cell cycle progression and morphology changes. Moreover, cAMP-PKA-CREB signaling can be influenced by PDE4D isoforms in peri- and intranuclear locations (i.e. PDE4D3, PDE4D5, and PDE4D9) to control cAMP-mediated transcriptional responses. This image was created using Biorender.

In general, long PDE4(D) isoforms share the ability to be phosphorylated by PKA which subsequently induces conformational changes leading to activation of these PDE4D isoforms (Hoffmann et al., 1998; Richter et al., 2005). By adopting different conformational states, PDE4 enzymes can also exhibit different affinities towards inhibitors (Paes et al., 2021). Historically, a high-affinity rolipram-binding state (HARBS) and low-affinity rolipram-binding state (LARBS) have been described, which can be bound specifically by different PDE4 types of PDE4 inhibitors (Rocque et al., 1997; Souness and Rao, 1997). Long PDE4(D) can dimerize and thereby stabilize the HARBS conformation (Richter and Conti, 2004). Interestingly, as inhibition of HARBS was found to stimulate neurite outgrowth whilst inhibition of LARBS did not (Boomkamp et al., 2014), these functional effects may also be contributing to inhibition of long PDE4D isoforms. Additional support for the role of long PDE4D isoforms in regulating neuronal plasticity and protection against  $A\beta_{1-42}$ -induced neurotoxicity was found by *in vivo* preclinical studies using shRNA-mediated knockdown of long PDE4D isoforms (Li et al., 2011; Shi et al., 2021b; Wang et al., 2013). Reassuringly, these studies found dendritic complexity, CREB signaling, and cognitive performance to be enhanced upon PDE4D long-form knockdown. These effects were ascribed to knockdown of PDE4D4 and PDE4D5 as qPCR indicated decreased expression of these forms. However, expression effects on other long PDE4D isoforms (i.e. PDE4D7, -D8 and -D9) were not reported although the shRNA sequence used would be expected to also cause degradation of these other isoforms (Li et al., 2011; Wang et al., 2013). Thus, knockdown of PDE4D7 and/or PDE4D9 might have contributed to the enhanced morphology complexity, CREB signaling and cognitive performance. The seemingly predominant role of long PDE4D isoforms in regulating neuroplasticity and cognition is further underlined by the association of mutations in *PDE4D* exons specific to long isoforms and the rare genetic disorder acrodysostosis, which is characterized by intellectual disability (Michot et al., 2018).

Strikingly, many of these mutations occur in protein domains that are unique to long PDE4D isoforms (Bolger, 2021).

The current findings also imply that the effects of pharmacological PDE4D inhibition on neurite growth are mediated by inhibition of long PDE4D forms specifically, which consequently has implications for PDE4D inhibitor drug development. The PDE4D inhibitor used in this study, GEBR32a, has been reported to show higher affinity for long, PKA-phosphorylated PDE4D forms, which may explain its efficacy (Cavalloro et al., 2020; Paes et al., 2021; Prosdocimi et al., 2018). Moreover, another example of a PDE4D long form-specific inhibitor is zatolmilast (formerly BPN14770) which binds a PDE4D-specific residue in a conformation that is adopted by long forms only (Burgin et al., 2010; Cedervall et al., 2015). Zatolmilast has shown efficacy in stimulating cAMP-PKA-CREB signalling and neuroplasticity in preclinical studies using wild-type animals and transgenic AD mice and enhances cognition in non-human primates (Cui et al., 2019; Sutcliffe et al., 2014). In fact, BPN14770/zatolmilast is under study in a Phase II clinical trial to assess its effects in early AD patients [NCT03817684].

While the results presented here show robustly that silencing of long PDE4D isoforms specifically enhances neuronal plasticity, the question remains whether these specific long PDE4D isoforms also mediate processes contributing to the adverse side effects associated with PDE4D inhibition. The molecular mechanisms underlying these side effects remain to be defined but seem to be induced by PDE4(D) inhibition in both the emetic brainstem regions as well as the gastrointestinal system (McDonough et al., 2020; Paes et al., 2021; Robichaud et al., 2002). Emesis-inducing cAMP signaling in the area postrema in the brainstem may rely on signaling downstream of the glucagon-like peptide 1 receptor (GLP1R) (Han and de Araujo, 2021; Zhang et al., 2021). Thus, it can be argued that the PDE4D isoforms that mediate cAMP signaling induced by GLP1Rs should not be inhibited to prevent these emetic brainstem regions from being activated. Remarkably, PDE4D5

has been linked to GLP1 release, but a possible link between PDE4D and GLP1-induced signal transduction upon GLP1R activation remains to be elucidated (Ong et al., 2009). Regarding peripherally-regulated side effects, it has recently been described that non-selective PDE4 inhibition induces gastroparesis (i.e. delayed gastric transit), which could subsequently trigger nausea and emesis (McDonough et al., 2020). However, it remains to be elucidated whether long isoforms of the different PDE4 subtypes predominantly mediate these processes. Encouragingly, we found here that not all (long) PDE4D isoforms are (equally high) expressed in the mouse stomach. Specifically, PDE4D3 and PDE4D5 exhibited high expression, whilst expression of PDE4D7 and PDE4D9 was substantially lower. Future studies could therefore investigate whether targeting of PDE4D7 and/or PDE4D9 as expressed in the brain would increase neuronal plasticity without contributing to stomach-mediated side effects that are associated with non-specific PDE4(D) inhibition.

## **CONCLUSION**

In summary, this study shows that inhibition of individual long PDE4D isoforms specifically enhances neuronal plasticity, and that inhibition of these isoforms can yield resilience against A $\beta$ -induced pathology in neurons. Hence, this target specification provides insights for the development of efficacious PDE4D inhibitors and supports the potential of PDE4D as a pharmacological target for the treatment of memory deficits in AD.

## ABBREVIATIONS

A $\beta$	Amyloid- $\beta$
AC	Adenylyl cyclase
AD	Alzheimer's disease
cAMP	Cyclic adenosine monophosphate
DISC1	Disrupted in schizophrenia 1
DMSO	Dimethyl sulfoxide
FAK	Focal adhesion kinase
GLP1R	Glucagon-like peptide 1 receptor
GPCR	G protein-coupled receptor
HARBS	High-affinity rolipram-binding state
HIP	Hippocampus
LARBS	Low-affinity rolipram-binding state
PDE	Phosphodiesterase
PFC	Prefrontal cortex
SNP	Single-nucleotide polymorphism
sAC	Soluble adenylyl cyclase
tmAC	Transmembrane adenylyl cyclase
VASP	Vasodilator-stimulated phosphoprotein

## ACKNOWLEDGMENTS

TV and JP have a proprietary interest in selective PDE4D inhibitors for the treatment of demyelinating disorders and neurodegenerative disorders. JP has a proprietary interest in the PDE4 inhibitor roflumilast for the treatment of cognitive impairment as well as PDE4D inhibitors for the treatment of Alzheimer's disease. OB, CB, EF, RR, JP have a proprietary interest in GEBR32a compound.

## ABSTRACT

Cyclic adenosine monophosphate (cAMP) is a generic signaling molecule that, through precise control of its signaling dynamics, exerts distinct cellular effects. Consequently, aberrant cAMP signaling can have detrimental effects. Phosphodiesterase 4 (PDE4) enzymes profoundly control cAMP signaling and comprise different isoform types of which the enzymatic activity is modulated by differential feedback mechanisms. Because these feedback dynamics are non-linear and occur coincidentally, their effects are difficult to examine experimentally, but can be well simulated computationally. Through understanding the role of PDE4 isoform types in regulating cAMP signaling, PDE4-targeted therapeutic strategies can be better specified. Here, we established a computational model to study how feedback mechanisms on different PDE4 isoform types lead to dynamic, isoform-specific control of cAMP signaling. Ordinary differential equations describing cAMP dynamics were implemented in the VirtualCell (VCell) environment. Simulations indicated that long PDE4 isoforms exert the most profound control on oscillatory cAMP signaling, as opposed to the PDE4-mediated control of single cAMP input pulses. Moreover, elevating cAMP levels or decreasing PDE4 levels revealed different effects on downstream signaling. Together these results underline that cAMP signaling is distinctly regulated by different PDE4 isoform types and that this isoform-specificity should be considered in both computational and experimental follow-up studies to better define PDE4 enzymes as therapeutic targets in diseases in which cAMP signaling is aberrant.

## **AUTHOR SUMMARY**

Cellular functioning relies on well-orchestrated intracellular signaling cascades. To sense and respond to the environment, cells relay extracellular signals to messenger molecules which can elicit adaptive responses. In response to different extracellular signals, cells often use the same messenger molecule, cyclic adenosine monophosphate (cAMP). By controlling the amplitude, duration and localization of this cAMP signaling, distinct messages can be relayed using the same signaling system. In disease, the well-orchestrated cAMP signaling can be impaired, causing unfavorable cellular responses. cAMP signaling is extensively controlled by phosphodiesterase 4 (PDE4) enzymes, which therefore provide a therapeutic target to restore aberrant cAMP signaling. PDE4 enzymes exist as different isoform types which control cAMP levels in similar, but distinct manners, as their enzymatic activity depends on dynamic feedback mechanisms. Experimentally, these highly dynamic feedback mechanisms and isoform-specific contribution to cAMP regulation are difficult to disentangle. Here, we investigated computationally which of the PDE4 isoform types exert(s) most control over cAMP signaling considering the aforementioned feedback mechanisms. Our results suggest that the so-called long PDE4 isoforms predominantly regulate cAMP signaling. Considering these findings, more specific targeting of long PDE4 types could achieve higher PDE4-mediated treatment efficacy in disease in which cAMP signaling is aberrant.

## INTRODUCTION

Sensing the environment and responding in an adaptive manner is crucial to cell survival and proper cell functioning. Relaying extracellular signals intracellularly to elicit an adaptive response therefore has to be tightly regulated in a dynamic, spatiotemporal manner. The pivotal intracellular signaling molecule cyclic adenosine monophosphate (cAMP) is synthesized by conversion of adenosine triphosphate (ATP) by both transmembrane and soluble adenylyl cyclases (AC). Although AC activity is regulated by a wide variety of receptors, it is striking that these receptors, responding to different extracellular cues, all lead to the production of the generic signaling molecule cAMP, which subsequently can bind different effector proteins. Among the cAMP effector proteins, protein kinase A (PKA) and exchange protein directly activated by cAMP (Epac) are most well-studied. PKA is a heterotetrameric protein complex that, upon binding cAMP, releases its catalytic subunits which can phosphorylate numerous target proteins (Herberg et al., 1996; Kim et al., 2007). Binding of cAMP to Epac releases the autoinhibitory conformation of Epac, which can initiate the activation of Rap1, a small GTPase of the Ras superfamily (de Rooij et al., 1998; Schmidt et al., 2013). Subsequently, Rap1 can influence a variety of cellular processes through modulation of various downstream proteins (Bos et al., 2001). Moreover, by binding Popeye domain containing proteins (POPDC) and cyclic nucleotide-gated channels (CNGC), cAMP signaling can modulate other biological functions (e.g. cell-cell adhesion and regulation of membrane potentials; reviewed in: (Kaupp and Seifert, 2002; Schindler and Brand, 2016)). Although these different effector proteins all respond to cAMP, through regulation of localization and the dynamics of the cAMP signal (e.g. its amplitude and duration), cAMP can distinctly influence different intracellular processes (Musheshe et al., 2018).

Intriguingly, the only way by which cAMP is enzymatically degraded, is via hydrolysis by phosphodiesterase (PDE) enzymes. In humans, eleven PDE gene families exist (PDE1-11) that can be classified based on their substrate selectivity;

some PDE types degrade cAMP selectively (PDE4,-7,-8) whilst others are selective to cyclic guanosine monophosphate (cGMP; PDE5,-6,-9). The remaining PDE types are dual-specific and degrade both cAMP and cGMP (PDE1,-2,-3,-10,-11). The different PDEs are heterogeneously distributed in a tissue- and cell-type specific manner (Baillie et al., 2019; Lakics et al., 2010). The PDE4 gene family comprises the largest amount of cAMP-specific PDEs and plays a critical role in shaping the dynamics and spatiotemporal control of cAMP signaling in many tissues and cell types (Baillie et al., 2019; Lakics et al., 2010). As pivotal regulators of cAMP signaling, PDE4 enzymes provide interesting pharmacological targets to modulate cAMP levels in a wide variety of disorders (Blokland et al., 2019; Paes et al., 2021; Peng et al., 2020). Consequently, PDE4 inhibition has been investigated as a therapeutic strategy to stimulate cAMP signaling. Although several PDE4 inhibitors are being used clinically, PDE4 inhibition may give rise to severe adverse effects (e.g. diarrhea, nausea, and emesis) for increasing doses. PDE4-mediated side effects are hypothesized to result, at least in part, from PDE4 inhibition in brainstem areas, and therefore more specific PDE4 inhibition is particularly required when, for the disease of interest, the therapeutic actions of PDE4 inhibition should occur in the brain (Paes et al., 2021). For example, in neurodegenerative disorder like Alzheimer's disease and multiple sclerosis, PDE4 inhibitors have to enter the central nervous system to exert therapeutic effect which makes these interventions also more prone to brainstem-mediated side effects (Blokland et al., 2019; Paes et al., 2021; Schepers et al., 2019). Therefore, a better understanding of how PDE4 mediates cAMP degradation is crucial to optimize PDE4 inhibition as a therapeutic strategy.

Human PDE4 enzymes are encoded by four genes (PDE4A-D) that each generate multiple isoforms (e.g. PDE4D1-9) through the use of alternative promoters and alternative splicing. Although the different isoforms are protein products with the same main biological function (i.e. cAMP hydrolysis), their protein sequence differences allow for isoform-specific localization and regulation of enzymatic activity

(Houslay, 2010; Paes et al., 2021). Specifically, PDE4 isoforms can be categorized as long, short, and supershort based on the presence of regulatory domains. These regulatory domains influence the functional effect of phosphorylation by different kinases including PKA and extracellular signal-regulated kinase (ERK) on PDE4 enzymatic activity (Paes et al., 2021). Long PDE4 isoforms are activated when phosphorylated by PKA (Alvarez et al., 1995; Hoffmann et al., 1998; MacKenzie et al., 2002; Sette and Conti, 1996; Sette et al., 1994), whilst being inhibited when phosphorylated by ERK (Baillie et al., 2000; Hoffmann et al., 1999; Lenhard et al., 1996; MacKenzie et al., 2000). In case of phosphorylation by both PKA and ERK, the ERK-mediated inhibition of long PDE4 forms will be relieved by concurrent phosphorylation by PKA (Hoffmann et al., 1999). Lacking the necessary regulatory domain, short PDE4 isoforms cannot be modulated by PKA but can be phosphorylated by ERK, resulting in enzyme activation. Similarly, supershort PDE4 isoforms can only be modulated by ERK, but in contrast to short isoforms, phosphorylation of ERK results in inhibition on supershort forms (Baillie et al., 2000). Importantly, while ERK may phosphorylate all PDE4 subtypes, this phosphorylation has only effects on the enzymatic activity of PDE4B, PDE4C, and PDE4D, but not PDE4A, forms due to the differences in amino acid sequence (Baillie et al., 2000; Lario et al., 2001; Paes et al., 2021). Interestingly, since PKA and ERK are activated downstream from cAMP signaling, their effects on PDE4 isoform activity act as feedback mechanisms on cAMP signaling (Figure 1). PKA is activated directly upon binding cAMP, whilst ERK is activated by intermediate signaling molecules downstream from cAMP. In fact, cAMP and ERK signaling are intricately linked in cell-type specific and cell-context dependent manners (reviewed in: (Stork and Schmitt, 2002)). Upon being activated by cAMP-bound Epac, Rap1 can initiate B-raf signaling which eventually activates ERK in specific cell types (Bos et al., 2001; Dugan et al., 1999; Hoy et al., 2020).

**Figure 1. Schematic representation of cAMP signaling cascades that influence PDE4-mediated cAMP degradation.** cAMP is created by conversion of ATP by adenylyl cyclases and is degraded by PDE4 enzymes to 5'-adenosine monophosphate (5'AMP). PDE4 enzymes comprise different isoform categories (i.e. long, short, and supershort) which are generated via the use of alternative promoters and alternative splicing from the four human PDE4 genes. The kinases PKA and ERK are activated downstream of cAMP and can influence the enzyme activity of PDE4 in an isoform-specific manner; long forms are activated upon phosphorylation by PKA, whilst phosphorylation by ERK causes inhibition of long and supershort PDE4 and activation of short PDE4. These feedback mechanisms contribute to the PDE4-mediated dynamic control of cAMP signaling. This figure was created with BioRender.com.

The fact that PDE4 isoforms show specific intracellular distribution patterns and their activity is dynamically and isoform-specifically regulated makes PDE4 isoforms crucial spatiotemporal regulators of cAMP signaling. Understanding the role of the different PDE4 isoform categories on this dynamic cAMP regulation will aid in determining which isoform type to inhibit to elicit the desired physiological effect. Consequently, inhibition of specific PDE4 isoforms may modulate cAMP signaling more effectively and may be therapeutically safer by inducing fewer or less severe side effects.

Signal termination, mediated by the different PDE4 isoform types, is critical in cAMP signaling and occurs very rapidly. This rapid termination makes experimental investigation of the role of specific PDE4 isoforms in spatiotemporal control of cAMP signaling difficult (Beavo and Brunton, 2002). Computational modeling of complex, dynamic biological mechanisms like cAMP signaling can overcome several experimental limitations while providing pivotal insights into the importance of specific molecules by considering cross-talk and feedback mechanisms. Various mechanistic computational models have been developed previously to understand cAMP signaling pathway dynamics. These models have investigated amongst others the diffusion and stochastic effects on the information flow through PKA signaling (Bhalla, 2004), the dynamics of calcium-induced cAMP signaling (Jędrzejewska-Szmek et al., 2017; Ohadi and Rangamani, 2019; Ohadi et al., 2019; Shumilov and Gotovtsev, 2021), the influence of receptor protein kinase and G-protein coupled receptor crosstalk (Getz et al., 2019), and the localization of cAMP signaling in subcellular domains (Kim et al., 2011; Oliveira et al., 2012; Stone et al., 2019; Tenner et al., 2020). Despite their important role in inactivating cAMP, cAMP-degrading PDE enzymes and their isoforms, which respond differently to feedback mechanisms, are not always included in the computational modeling efforts. Some models have studied the influence of PDE4 (Chay et al., 2016), PDE4 and PDE1 (Kim et al., 2011; Lindskog et al., 2006; Ohadi and Rangamani, 2019; Ohadi et al., 2019), and PDE1 and PDE10 (Oliveira et al., 2012). Others have investigated theoretically how a single PDE or PDE complexes can create cAMP nanocompartments and how these depend on the cAMP degradation rate, cAMP diffusion rate and geometrical and topological parameters (Lohse et al., 2017). Only the framework of Oliveira et al. specifically modeled two different subtypes of PDE4, i.e. PDE4B (located in the submembrane region) and PDE4D (located in the cytosol), the most prevalent isozymes in HEK293 cells (Oliveira et al., 2010). Their simulation results demonstrated that the generation of a cAMP microdomain required a pool of PDE4D anchored in the cytosol as well as

a PKA-mediated increase of PDE4D activity. Interestingly, cAMP microdomains did not require impeded diffusion of cAMP (Oliveira et al., 2010). To our knowledge, the influence of feedback mechanisms on general, but not isoform-specific, PDE4 activity has only been described by Song et al. (Song et al., 2013).

In this study, we model the dynamics of cAMP signaling and investigate the involvement of specific PDE4 isoform types, i.e. long, short and supershort, and the PKA/ERK feedback thereon, in the modulation of cAMP signaling dynamics. Using a computational approach we intend to better understand and conceptualize the signaling feedback mechanisms that differentially modulate the PDE4 isoform activity to determine which PDE4 isoform type may provide a more efficacious target in diseases in which PDE4 inhibition shows therapeutic potential.

## **MATERIALS AND METHODS**

### **Mathematical model development**

To simulate isoform-specific PDE4-mediated control of cAMP dynamics, a mathematical model was developed and implemented in the virtual cell environment VCell (<http://vcell.org>) (Slepchenko and Loew, 2010). Fifteen ordinary differential equations were established which describe the dynamics of cAMP, PDE4, PKA, Epac and RAP-1/ERK signaling in time. The following sections describe the mathematical framework of the model, the reactions and corresponding kinematic parameters. Figure 2 shows a schematic of the variables included in the model and their interactions.

### **Parameter values and initial conditions**

Considering the high diffusion capability of free, unbound cAMP (Bock et al., 2020; Yang et al., 2016), we modelled the system as well-mixed using ordinary differential equations, which are listed, including initial concentrations, in Table 1. We also assume that all downstream, inactivated components are not present at the start of the simulation. All reactions and corresponding parameters are given in Tables 2 and 3. All reactions are assumed to be reversible, except the irreversible degradation of cAMP and phosphorylation-based actions on PDE4 isoforms.

**Figure 2: Schematic representation of the molecular reactions incorporated in the computational model.** cAMP is modelled as an initial condition and is degraded to 5'AMP by different PDE4 isoforms (long, short, and supershort) that each can exhibit different degradation rates (e.g.  $K_{12_{on}PDE}$ ). If not degraded, cAMP can bind and activate the tetramer PKA ( $PKA_{tet}$ ) to form C1, which causes  $PKA_{cat}$  subunits to be released ( $PKA_{cat,1}$ ). Similarly, cAMP can bind and activate Epac to form  $Epac_{ON}$ , which can convert  $RAP1_{GDP}$  into  $RAP1_{GTP}$  to eventually elicit ERK phosphorylation and dimerization (ppERK).  $PKA_{cat,1}$  and ppERK can modulate PDE4 isoform activity and thereby provide feedback mechanisms of cAMP signaling.

**Table 1. Overview of reaction species, ordinary differential equations (ODE) and initial concentrations**

#	Species	Description	Ordinary differential equation	Initial concentration ( $\mu\text{M}$ )	Reference for the used initial concentration
1	[cAMP]	cAMP concentration	$\frac{dcAMP}{dt} = -(k_{on,PDE} + k12_{on,PDE} + k13_{on,PDE}) \cdot cAMP \cdot PDE4_{long} - (k_{on,PDE} + k22_{on,PDE} + k23_{on,PDE}) \cdot cAMP \cdot PDE4_{short} - (k_{on,PDE} + k32_{on,PDE} + k33_{on,PDE}) \cdot cAMP \cdot PDE4_{supershort} - 4 \cdot k_{on,C1} \cdot \frac{PKA \cdot cAMP^{1.6}}{k_m^{1.6} PKA + cAMP^{1.6}} + 4 \cdot k_{deg} \cdot C_1 - k_{on,EPAC} \cdot \frac{EPAC \cdot cAMP}{k_m EPAC + cAMP} + k_{off,EPac} \cdot Epac_{on}$	0.3 (standard) or cyclic input (see text)	(Agarwal et al., 2016), (Jedrzejewska-Szmek et al., 2017)
2	[AMP]	AMP concentration	$\frac{dAMP}{dt} = (k_{on,PDE} + k12_{on,PDE} + k13_{on,PDE}) \cdot cAMP \cdot PDE4_{long} + (k_{on,PDE} + k22_{on,PDE} + k23_{on,PDE}) \cdot cAMP \cdot PDE4_{short} + (k_{on,PDE} + k32_{on,PDE} + k33_{on,PDE}) \cdot cAMP \cdot PDE4_{supershort}$	0	(Neves et al., 2008)
3	[PDE4]	PDE4 concentration	constant	1 (standard) (hippocampal proportions, PDE4 <sub>long</sub> : 0.7; PDE4 <sub>short</sub> : 0.11; PDE4 <sub>supershort</sub> : 0.19)	(Neves et al., 2008) <b>(Supplementary Material)</b>
4	[PKA <sub>cat</sub> ]	PKA catalytic subunits	$\frac{dPKA_{cat}}{dt} = -2 k_{on,PKA} \cdot PKA_{cat}^2 \cdot PKA_{reg}^2 + k_{deg,1} \cdot PKA_{cat,1} + 2k_{off,PKA} \cdot PKA_{tet}$	0.023	(Oliveira et al., 2010)
5	[PKA <sub>reg</sub> ]	PKA regulatory subunits	$\frac{dPKA_{reg}}{dt} = -2k_{on,PKA} \cdot PKA_{reg}^2 \cdot PKA_{cat}^2 + 2k_{off,PKA} \cdot PKA_{tet} + 2k_{deg} \cdot C_1$	0.048	(Oliveira et al., 2010)
6	[PKA <sub>tet</sub> ]	PKA tetramer	$\frac{dPKA_{tet}}{dt} = k_{on,PKA} \cdot PKA_{cat}^2 \cdot PKA_{reg}^2 - k_{off,PKA} \cdot PKA_{tet} - k_{on,C1} \cdot \frac{PKA_{tet} \cdot cAMP^{1.6}}{k_m^{1.6} PKA + cAMP^{1.6}}$	0.173	(Neves et al., 2008; Ohadi et al., 2019)
7	[C1]	cAMP-bound PKA tetramer	$\frac{dC1}{dt} = k_{on,C1} \cdot \frac{PKA_{tet} \cdot cAMP^{1.6}}{k_m^{1.6} PKA + cAMP^{1.6}} - k_{deg} \cdot C1$	0	Model assumption
8	[PKA <sub>cat1</sub> ]	active PKA catalytic subunit	$\frac{dPKA_{cat1}}{dt} = 2k_{deg} \cdot C_1 - k_{deg,1} \cdot PKA_{cat,1}$	0	(Oliveira et al., 2010)
9	[EPAC]	inactivated Epac	$\frac{dEPAC}{dt} = -k_{on,EPAC} \cdot \frac{EPAC \cdot cAMP}{k_m EPAC + cAMP} + k_{off,EPac} \cdot Epac_{on}$	0.488	(Jedrzejewska-Szmek et al., 2017; Salonikidis et al., 2008)

#	Species	Description	Ordinary differential equation	Initial concentration (μM)	Reference for the used initial concentration
10	[EPAC <sub>on</sub> ]	cAMP-bound, activated Epac	$\frac{dEPAC_{on}}{dt} = k_{on,EPAC} \cdot \frac{EPAC \cdot cAMP}{k_m EPAC + cAMP} - k_{off,Epac} \cdot Epac_{on} - k_{onRAP1} \cdot Epac_{on} \cdot RAP1_{GDP} + k_{offRAP1} \cdot RAP1_{GTP}$	0	(Jedrzejewska-Szmek et al., 2017)
11	[RAP1 <sub>GDP</sub> ]	inactive Rap1	$\frac{dRAP1_{GDP}}{dt} = -k_{on,RAP1} \cdot Epac_{on} \cdot RAP1_{GDP} + k_{off,RAP1} \cdot RAP1_{GTP}$	0.2	(Sasagawa et al., 2005)
12	[RAP1 <sub>GTP</sub> ]	active Rap1	$\frac{dRAP1_{GTP}}{dt} = k_{on,RAP1} \cdot Epac \cdot RAP1_{GDP} - k_{off,RAP1} \cdot RAP1_{GTP} - k_{on,ERK} \cdot RAP1_{GTP} \cdot ERK + k_{off} \cdot ppERK$	0	Model assumption
13	[ERK]	ERK concentration	$\frac{dERK}{dt} = -k_{on,ERK} \cdot ERK \cdot RAP1_{GTP} + k_{off,ERK} \cdot ppERK$	0.8	(Zhang et al., 2011)
14	[ppERK]	activated ERK	$\frac{dppERK}{dt} = k_{on,ERK} \cdot ERK \cdot RAP1_{GTP} - k_{off,ERK} \cdot ppERK + 2 \cdot k_{off,dimer} \cdot ERK_{dimer} - 2k_{on,dimer} \cdot ppERK^2$	0	Model assumption
15	[ERK <sub>dimer</sub> ]	dimerized ERK	$\frac{dERK_{dimer}}{dt} = k_{on,dimer} \cdot ppERK^2 - k_{off,dimer} \cdot ERK_{dimer}$	0	Model assumption

### **cAMP and PDE4 dynamics**

cAMP signaling is initiated by the synthesis of cAMP by activated adenylyl cyclases. Since the primary focus of this study is the role of different PDE4 isoforms on cAMP signaling, we investigate three types of initial cAMP conditions: 1) an initial pulse of 0.1, 0.3, 1 or 3  $\mu\text{M}$  and 2) a continuous, cyclic input of cAMP specified as follows:

$$cAMP_{input} = 0.45 \cdot |\sin(0.015t)| \cdot (0.9998^t) + 0.3$$

which reflects the cAMP oscillations reported by Ohadi et al. (Ohadi et al., 2019) and 3) a ramp function of cAMP input defined as follows:

$$cAMP_{input} = 0.001 \cdot t \ (t < 300) + 0.3 \ (t > 300)$$

resulting in a gradual, time-dependent increase over 300s (Calebiro et al., 2009) until a constant input of 0.3  $\mu\text{M}$ , mimicking a sustained plateau of adenylyl cyclase activation. Note that we do not model adenylyl activity explicitly here.

We simulate in the computational model the PDE4-mediated enzymatic inactivation of cAMP (Table 1: Equations 1-2). Moreover, we model the total initial amount of all PDE4 isoforms combined as constant and equal to 1  $\mu\text{M}$  (Table 1: Equations 3) (Neves et al., 2008). The relative distribution of the PDE4 isoforms is modeled as follows: 70% long PDE4 isoform, 11% short PDE4 isoform and 19% supershort PDE4 isoform. These distributions are based on in-house measurements of rat hippocampal tissue to exemplify tissue-specific isoform proportions (see Supplementary Material). Since long PDE4 isoforms comprise 70% of the total in this tissue, the effect of long PDE4 isoforms on cAMP signaling may be biased by the fact that these long forms are most abundantly present. As such, we control for this potential bias by also investigating a scenario in which the isoforms have equal proportions. More specifically, one isoform is set to zero and the other isoforms are

both present at 0.5  $\mu\text{M}$  concentration in order to keep the total PDE4 concentration constant at 1  $\mu\text{M}$  (Figure 10). In the computational model, cAMP degradation is modelled with mass action kinetics, and has three contributions: 1) baseline degradation by PDE4 that is independent of isoform type, 2) isoform-specific modulation of the baseline degradation by the activated catalytic subunit of PKA ( $\text{PKA}_{\text{cat},1}$ ), and 3) isoform-specific modulation of the baseline degradation by activated ERK ( $\text{ERK}_{\text{dimer}}$ ) (Table 1: Equations 1-2).

The activated catalytic subunit of PKA ( $\text{PKA}_{\text{cat},1}$ ) and activated ERK ( $\text{ERK}_{\text{dimer}}$ ) are modeled to influence cAMP degradation rate by activating or inhibiting PDE4, depending on the PDE4 isoform involved (Paes et al., 2021). Therefore,  $k12_{\text{on},\text{PDE}}$ ,  $k13_{\text{on},\text{PDE}}$ ,  $k22_{\text{on},\text{PDE}}$ ,  $k23_{\text{on},\text{PDE}}$ ,  $k32_{\text{on},\text{PDE}}$  and  $k33_{\text{on},\text{PDE}}$  are not constant but depend on  $\text{PKA}_{\text{cat},1}$  or  $\text{ERK}_{\text{dimer}}$ , which can have an inhibitory ( $V_{\text{max}}$  is negative) or stimulating ( $V_{\text{max}}$  is positive) effect depending on the affected PDE4 isoform. These phosphorylation-based activity effects were modeled with a Michaelis-Menten function as:

$$ki2_{\text{on},\text{PDE}} = \frac{v_{\text{max}i} \cdot \text{PKA}_{\text{cat}1}}{k_{m1i} + \text{PKA}_{\text{cat}1}} \quad \text{and} \quad ki3_{\text{on},\text{PDE}} = \frac{v_{\text{max}i} \cdot \text{ERK}_{\text{dimer}}}{k_{m1i} + \text{ERK}_{\text{dimer}}}$$

with  $i = 1, 2, 3$

(Eq. 1)

Phosphorylation by PKA or ERK changes the rate of cAMP hydrolysis by PDE4 by changing  $V_{\text{max}}$  without affecting  $k_m$  (Hoffmann et al., 1999; Hoffmann et al., 1998). Moreover, it has been reported that the  $k_m$  values for different PDE4 forms are similar (Bolger et al., 1996; Jin et al., 1992; Saldou et al., 1998). It has been reported that the measured basal  $V_{\text{max}}$  ( $8 \cdot \text{s}^{-1}$ ) is increased to 272% due to phosphorylation by PKA and reduced by 75% due to phosphorylation by ERK in case of the long isoform (Hoffmann et al., 1999; Hoffmann et al., 1998). The basal activity of the short isoform and supershort isoforms are increased to 130% and reduced to 85% respectively due to phosphorylation by ERK (Baillie et al., 2000). We would like to highlight that some literature reports mention a % reduction in the  $V_{\text{max}}$  value and others an overall

activity reduction with respect to the baseline value. Here we have chosen to adapt the basal  $V_{max}$  value (taken as  $8 \text{ s}^{-1}$  based on (Bolger et al., 1997; Lim et al., 1999; Neves et al., 2008; Reeves et al., 1987)). For example, a 272% increase in the  $V_{max}$  of long isoform mutated to mimic PKA phosphorylation has been reported (Hoffmann et al., 1999), which we captured via a  $V_{max}$  of 21.76 (i.e.  $k_{12_{on,PDE}}$ ). A similar reasoning was made for the other  $V_{max}$  values (Hoffmann et al., 1999; MacKenzie et al., 2000). Parameters used for each isoform are given in Table 2. We also implemented that  $k_{13_{on,PDE}}$  and  $k_{33_{on,PDE}}$  cannot become larger than the baseline PDE4 degradation rate ( $k_{on,PDE}$ :  $0.15 \mu\text{M}\cdot\text{s}^{-1}$ ), as this would result in 'negative degradation' and therefore 'production' of cAMP. The degradation of cAMP into AMP is assumed to be irreversible as cAMP can only be synthesized by conversion of ATP via ACs.

**Table 2. Kinematic parameters used to model activity of PDE4 isoforms upon phosphorylation by PKA and ERK**

Parameter	Description	$k_m$ ( $\mu\text{M}$ )	$V_{max}$ ( $\mu\text{M}^{-1}\cdot\text{s}^{-1}$ )	$V_{max}$ %	References
$k_{on,PDE}$	Baseline PDE4 degradation rate	/	0.15	(mass action kinetics)	(Neves et al., 2008)
$k_{12_{on,PDE}}$	PDE4 long PKA-phosphorylated	1.3	21.76	272%	(Hoffmann et al., 1999)
$k_{13_{on,PDE}}^*$	PDE4 long ERK-phosphorylated	1.3	-2	25%	(Hoffmann et al., 1999)
$k_{22_{on,PDE}}$	PDE4 short PKA-phosphorylated	0	0		
$k_{23_{on,PDE}}$	PDE4 short ERK-phosphorylated	1.3	10.4	130%	(MacKenzie et al., 2000)
$k_{32_{on,PDE}}$	PDE4 supershort PKA-phosphorylated	0	0		
$k_{33_{on,PDE}}^*$	PDE4 supershort ERK-phosphorylated	1.3	-6.8	85%	(MacKenzie et al., 2000)

\* $k_{13_{on,PDE}}$  and  $k_{33_{on,PDE}}$  cannot become larger than  $k_{on,PDE}$  ( $0.15 \mu\text{M}\cdot\text{s}^{-1}$ ), the baseline PDE4 degradation rate ( $k_{on,PDE}$ ).

## PKA dynamics

PKA activation by cAMP is modelled as a multistep process using mass action kinetics. The inactive tetramer PKA ( $PKA_{tet}$ ) is formed by the association of two catalytic ( $PKA_{cat}$ ) and two regulatory subunits ( $PKA_{reg}$ ) with constant  $k_{on,PKA}$ . We assume that four cAMP molecules can bind cooperatively to the tetramer with a Hill coefficient of 1.6 (Kim et al., 2007; Zhang et al., 2015), to form a complex (C1). When C1 dissociates (with constant  $k_{deg}$ ), the active catalytic subunits ( $PKA_{cat,1}$ ) are released. Inactivation of the active catalytic subunits ( $PKA_{cat,1}$ ) occurs at a constant rate  $k_{deg,1}$ , after which the catalytic subunits can re-associate with the regulatory subunits to form the PKA tetramer,  $PKA_{tet}$  (Fig. 2 and Table 1: Equations 4-8).

At basal cAMP levels PKA activity has been found to be absent (Koschinski and Zacco, 2017). We therefore assumed that cAMP was only able to significantly bind PKA when cAMP levels were higher than  $5.2 \mu M$  (Koschinski and Zacco, 2017), which we modelled by putting  $k_{mPKA}$  to  $5.2 \mu M$  (Table 1, Equation 7).

## Epac-RAP1-ERK dynamics

Epac is a guanine nucleotide exchange factor (GEF) that aids in the activation of Rap1 (Bos et al., 2001; de Rooij et al., 1998; Schmidt et al., 2013). In the model, the binding of cAMP to Epac with rate constant  $k_{on,Epac}$  releases Epac from its auto-inhibitory conformation (EPAC), producing  $EPAC_{on}$  (Table 1: Equations 9-10). We assumed that Epac could only be significantly activated at cAMP concentrations higher than  $30 \mu M$ , which we captured by setting  $k_{mEPAC}$  to  $30 \mu M$  (Table 1, Equation 9) (Purves et al., 2009). Subsequently,  $EPAC_{on}$  is able to activate Rap1, which is mathematically represented in Table 1: Equations 11-12. Rap1 can, through complex, cross-talking signaling cascades, modulate ERK activation (Bos et al., 2001; Dugan et al., 1999; Stork and Schmitt, 2002). Since PDE4 inhibitors that should exert therapeutic actions in the brain are also prone to induce PDE4-mediated side effects by actions in the brainstem, we sought to better understand PDE4-mediated cAMP degradation in neurons specifically. In neurons, cAMP increases ERK activity in an

Rap1/B-raf dependent manner (Dugan et al., 1999). Here, we assume that Rap1 directly activates ERK, as intermediate signaling via B-raf and MEK consists of linear reactions. ERK is activated after its dual phosphorylation and subsequent dimerization (Fig. 2 and Table 1: Equations 13-15). ERK dimerization is crucial for extranuclear/cytosolic actions, and PDE4 was found to associate with ERK2 dimers and not with monomers (Casar et al., 2008; Herrero et al., 2015). Subsequently, the ERK<sub>dimer</sub> is able to phosphorylate PDE4 isoforms and stimulate or inhibit their rate isoform-specifically (Equation 1 and Table 2) (Houslay and Baillie, 2003).

### **Simulation settings**

Simulations were run in VCell, for a duration of 500 or 1500s with a combined stiff solver (IDA/CVODE). The absolute and relative tolerance was set to  $1 \cdot 10^{-9}$ . The models for a single pulse and continuous input, can be accessed on the VCell public model repository <https://vcell.org/vcell-published-models>. The names of the models are as follows, for a single pulse: Carlier\_cAMP\_isoforms\_v2; and for continuous, cyclic input: Carlier\_cAMP\_isoforms\_cyclic\_v2.

Details on running a model in VCell can be found in the quick start guide on the VCell website, <https://vcell.org/support>. Data was analyzed using GraphPad Prism V9.1.0.

**Table 3: Reactions and kinetic parameters**

#	Reaction	Rate constants	Value	Reference
1	$\text{cAMP} \xrightarrow{\text{kon, PDE; PDE}} \text{AMP}$	$k_{\text{on,PDE}}$	$0.15 \mu\text{M}^{-1} \text{s}^{-1}$	(Xin et al., 2008)
2	$2\text{PKA}_{\text{cat}} + 2\text{PKA}_{\text{reg}} \rightleftharpoons \text{PKA}$	$k_{\text{on,PKA}}$ $k_{\text{off,PKA}}$	$10 \mu\text{M}^{-2} \text{s}^{-1}$ $6 \cdot 10^{-4} \text{s}^{-1}$	Estimated
3	$\text{PKA} + 4\text{cAMP} \xrightarrow{\text{kon, C1}} \text{C}_1$	$k_{\text{on,C1}}$ $k_{\text{m,PKA}}$	$0.0261 \text{s}^{-1}$ $5.2 \mu\text{M}$	(Jedrzejewska-Szmek et al., 2017) (Koschinski and Zaccolo, 2017)
4	$\text{C}_1 \xrightarrow{k_{\text{deg}}} 2\text{PKA}_{\text{cat},1} + 2\text{PKA}_{\text{reg}} + 4\text{cAMP}$	$k_{\text{deg}}$	$0.21 \text{s}^{-1}$	(Ohadi et al., 2019)
5	$\text{PKA}_{\text{cat},1} \xrightarrow{k_{\text{deg},1}} \text{PKA}_{\text{cat}}$	$k_{\text{deg},1}$	$0.0051 \text{s}^{-1}$	(Jedrzejewska-Szmek et al., 2017)
6	$\text{Epac} + \text{cAMP} \rightleftharpoons \text{Epac}_{\text{on}}$	$k_{\text{on,Epac}}$ $k_{\text{off,Epac}}$ $k_{\text{m,Epac}}$	$0.031 \text{s}^{-1}$ (estimated) $0.00651 \text{s}^{-1}$ $30 \mu\text{M}$	(Jedrzejewska-Szmek et al., 2017) (Purves et al., 2009)
7	$\text{Epac}_{\text{on}} + \text{RAP1}_{\text{GDP}} \rightleftharpoons \text{RAP1}_{\text{GTP}}$	$k_{\text{on,RAP1}}$ $k_{\text{off,RAP1}}$	$0.05 \mu\text{M}^{-1} \text{s}^{-1}$ (estimated) $1.166 \cdot 10^{-4} \text{s}^{-1}$	(Sasagawa et al., 2005)
8	$\text{RAP1}_{\text{GTP}} + \text{ERK} \rightleftharpoons \text{ppERK}$	$k_{\text{on,ERK}}$ $k_{\text{off,ERK}}$	$0.88 \mu\text{M}^{-1} \text{s}^{-1}$ $0.088 \text{s}^{-1}$	(Fujioka et al., 2006; Radhakrishnan et al., 2009)
9	$\text{ppERK} + \text{ppERK} \rightleftharpoons \text{ERK}_{\text{dimer}}$	$k_{\text{on,dimer}}$ $k_{\text{off,dimer}}$	$0.2 \mu\text{M}^{-1} \text{s}^{-1}$ $0.0015 \text{s}^{-1}$	Estimated based on $K_d = 7.5 \text{nM}$ (Khokhlatchev et al., 1998)

### **Sensitivity analysis**

A sensitivity analysis was performed on the standard model where the Vmax parameter values were altered to investigate which Vmax was most influential on the average and maximal cAMP values over 1500 seconds for cyclic input (see Figure S3). The sensitivity was calculated as follows:

$$\text{Sensitivity} = \frac{|cAMP(k) - cAMP(k + \Delta k)|}{cAMP(k + \Delta k)} / \frac{\Delta k}{k}$$

where,

cAMP (k) = the maximal or average cAMP concentration over 1500 seconds for cyclic input using the standard model settings

cAMP (k+Δk)= the maximal or average cAMP concentration over 1500 seconds for cyclic input at + or - 10% of the standard Vmax model parameter values

Δk=varied parameter

k=standard model parameter value

## RESULTS

### Degradation dynamics of a single cAMP pulse

Different initial cAMP concentrations (0.1-3.0  $\mu\text{M}$ ) were used in the simulations to explore potential concentration-dependent effects on cAMP degradation (Figure 3). Irrespective of the initial cAMP concentration, single cAMP pulses were completely degraded within 25 s. Comparison of the degradation rates revealed that initial cAMP concentrations of 1.0 and 3.0  $\mu\text{M}$  induced a higher degradation rate compared to lower initial cAMP concentrations (Fig 3A, insert). Note that increases in initial cAMP concentrations are not proportional to the amount of cAMP present over time (reflected by the areas under the curve (AUC), Fig 3B). For example, for a pulse of 3.0  $\mu\text{M}$  cAMP, a fold change of 10 would be expected whilst a fold change of 8.17 is observed, which indicates that higher initial cAMP concentrations elicit additional effects to facilitate its own degradation.

**B**

cAMP		Fold changes		
cAMP condition	0.33	Time to peak	Peak	AUC
0.1 μM cAMP	0.33	1	0.33	0.34
0.3 μM cAMP	1	1	1	1
1.0 μM cAMP	3.33	1	3.33	3.17
3.0 μM cAMP	10	1	10.00	8.17

**Figure 3. Degradation dynamics of single cAMP pulses of different concentration predicted by the computational model.** A) Single cAMP pulses in a concentration range of 0.1-3.0  $\mu\text{M}$  are quickly degraded for all simulated concentrations. In the insert, degradation rates are compared by log-transformation of the y-axis showing equal degradation rates for cAMP concentration of 0.1-1.0  $\mu\text{M}$  and profound increased degradation of cAMP in case of an initial concentration of 3  $\mu\text{M}$  cAMP. B) Overview of plot characteristics per initial cAMP concentration. Fold changes in initial cAMP concentration, time to peak, peak value, and area under the curve (AUC) are shown compared to the 0.3  $\mu\text{M}$  cAMP condition. These values indicate that the AUC does not change proportionally to the change in initial cAMP concentration. Simulations were run for 500 s considering estimated hippocampal PDE4 isoform proportions and a total initial (constant) amount of all PDE4 isoforms combined equal to 1  $\mu\text{M}$ .

### **Effects of different cAMP concentrations on PKA, Epac, and ERK dynamics**

Although distinct cAMP pulse concentrations were all found to be quickly degraded based on our initial simulations, we next sought to explore how downstream signaling cascades are affected by these different initial cAMP concentrations. In our computational model, we have focused on the downstream cAMP-PKA and cAMP-Epac-ERK pathways as PKA and ERK affect cAMP signaling using feedback mechanisms through the modulation of PDE4 enzyme activity. In the following sections, the mentioning of PKA, Epac, and ERK reflects concentrations of the species  $PKA_{cat,1}$ ,  $Epa_{CON}$ , and  $ERK_{dimer}$ , respectively.

Simulations using single cAMP pulses of different concentrations revealed that PKA and Epac are differentially activated depending on the cAMP concentration. For example, cAMP pulses of 0.3 and 1.0  $\mu$ M lead to slightly higher peak activation of Epac compared to PKA, whilst a cAMP pulse of 3.0  $\mu$ M induces profoundly higher peaks of PKA compared to Epac (Fig 4A,B,D,E). Moreover, a distinction in PKA and Epac dynamics can be observed regarding their concentrations over time. Irrespective of the concentration cAMP, PKA levels subside more slowly compared to Epac (Fig 3A,B). ERK signaling is only activated if Epac is sufficiently activated (Fig 4 and Fig 2 in Material and Methods). Higher initial cAMP levels resulted profoundly higher  $ERK_{dimer}$  concentrations until the endpoint of the simulation (500 s) (Fig 4C,F).

**Figure 4. Activation dynamics of downstream signaling by different cAMP concentrations predicted by the computational model.** Single cAMP pulses in a concentration range of 0.1-3.0  $\mu\text{M}$  induced dose-dependent increases in PKA activation (A), Epac activation (B) and ERK activation (C). cAMP concentrations differentially affect PKA and Epac signaling as shown by differences in proportional peak height, time to peak and AUC differences for the various cAMP concentrations compared to the default model using 0.3  $\mu\text{M}$  cAMP as initial concentration (D-E). ERK activation did not reach a plateau during the 500 s simulation, but shows non-linear increases as higher initial cAMP concentrations were simulated (C, F). PKA, Epac and ERK reflect the model species PKAcat,1, EpacON, and ERKdimer, respectively. Simulations were run for 500 s considering estimated hippocampal PDE4 isoform proportions.

## **Effects of PDE4 concentrations and isoform type on single pulse cAMP signaling**

Corresponding to literature, cAMP is rapidly degraded in the computational model after a single cAMP pulse (Fig. 3). PDE4 enzymes play a pivotal role the regulation of cAMP signaling. To explore the effect of PDE4-mediated cAMP regulation, simulations were run using different concentrations of total PDE4 enzyme. Total PDE4 enzyme concentrations ranged from 0.1 to 10  $\mu\text{M}$ , while taking into account the relative proportions of PDE4 isoform types as measured in the rat hippocampus as an example of organ-specific PDE4 isoform type expression (Supplementary Material). Relative proportions of long (0.70), short (0.11), and supershort (0.19) isoforms were kept constant for all total PDE4 concentrations. As expected, higher total PDE4 concentrations resulted in a more rapid degradation of a single 0.3  $\mu\text{M}$  cAMP pulse (Fig. 5A). Dynamics of downstream PKA, Epac, and ERK signaling were highly non-linear for different PDE4 concentrations (Fig. 5B-D). For example, compared to the default total PDE4 concentration of 1  $\mu\text{M}$ , higher PDE4 concentrations (3-10  $\mu\text{M}$ ) lead to 3- and 10-fold lower AUC values for cAMP, PKA and Epac. In contrast, lower PDE4 concentrations cause non-proportional increases in peak and AUC values for cAMP, PKA and Epac (Fig 5B,C,F). For example, a 10-fold higher initial cAMP pulse (3.0  $\mu\text{M}$ ) causes a 28.56- and 8.29-fold increase in the peak value for PKA and Epac, respectively. Regarding ERK activation, non-linear effects are observed for both lower and higher total PDE4 concentrations, implying ERK levels are particularly sensitive to the amount of PDE4 present (Fig 5D,F).

Interestingly, downstream signaling cascades appear to respond differently to increases in initial cAMP pulses versus reductions in the amount of PDE4 present when comparing to the default model in which an initial cAMP pulse of 0.3  $\mu\text{M}$  is simulated with 1  $\mu\text{M}$  PDE4 present. Specifically, a 10-fold increase in initial cAMP concentration causes a larger fold change in AUC value and peak value for PKA (PKA peak: 28.56 and AUC: 28.31; Fig 4D) compared to a 10-fold decrease in PDE4 concentration (PKA peak: 6.74 and AUC: 8.66; Fig 5F). In contrast, a 10-fold increase

in initial cAMP concentration causes a smaller fold change in AUC value for Epac (Epac AUC: 7.79; Fig 4E) compared to a 10-fold decrease in PDE4 concentration (Epac AUC: 8.89; Fig 5F). Moreover, changing the PDE4 concentration resulted into a more profound effect on the fold changes in time to peak for PKA and Epac (i.e. fold changes ranging 0.18-3.72; Fig 5F) compared to changes in cAMP input concentrations (i.e. fold changes ranging 0.81-1.04; Fig 4D,E). These findings indicate that changes in cAMP input or PDE4-mediated cAMP degradation differentially affect the amplitude and timing of activation of downstream signaling.

Because the enzyme activity of PDE4 isoform types is differentially altered by PKA and ERK feedback phosphorylation, we subsequently investigated whether the presence of a single PDE4 isoform type at a concentration of 1.0  $\mu\text{M}$ , rather than a combination of them in specific proportions, resulted in isoform-specific dynamics of 0.3  $\mu\text{M}$  cAMP pulse degradation. Unexpectedly, cAMP degradation was found to be identical irrespective of the PDE4 isoform type present (Fig. 5E). These results suggest that, for a single pulse, the rate of cAMP degradation is determined by the total isoform concentration rather than the isoform type present or the relative proportion of multiple types.

**Figure 5. The influence of PDE4 concentration and isoform type on single pulse cAMP signaling as predicted by the computational model.** A) Degradation of a single 0.3  $\mu$ M cAMP pulse is dependent on the concentration of total PDE4 present. Relative proportions of long, short and supershort PDE4 isoforms were kept constant. B-D) Lower total PDE4 concentrations induced higher peaks, increased time to peak and sustained activation of PKA, Epac and ERK. E) Simulations in which total PDE4 consists of only a specific PDE4 isoform type indicated that all PDE4 isoform types degrade a single 0.3  $\mu$ M cAMP pulse identically. F) Fold changes in time to peak, peak and area under the curve (AUC) are listed for the different PDE4 concentration conditions, compared to the 1.0  $\mu$ M PDE4 condition, for cAMP and for the downstream signaling molecules PKA, Epac, and ERK. PKA, Epac and ERK reflect the species  $PKA_{cat,1}$ ,  $Epa_{CON}$ , and  $ERK_{dimer}$ , respectively. Simulations were run for 500 s considering, except for Fig 4E, estimated hippocampal PDE4 isoform proportions.

### **Dynamics of oscillatory cAMP signaling and isoform-specific control by PDE4**

Following up on the unexpected finding that different PDE4 isoform types show identical dynamics of single cAMP pulse degradation when present at the same concentration, we hypothesized that single cAMP pulses may not be sufficient to elicit the PKA- and ERK-based feedback mechanisms on PDE4 activity as observed in cell-based experiments. Accordingly, under physiological conditions cAMP synthesis occurs in a prolonged, oscillatory manner rather than as the production of single cAMP pulses (Dyachok et al., 2006; Huff et al., 2020). Previous studies have shown that calcium oscillates spontaneously and that these oscillations influence the cAMP/PKA dynamics (Chen et al., 2013; Ohadi et al., 2019). In particular, computational work has shown that cAMP/PKA is a leaky integrator of calcium dynamics, meaning that cAMP/PKA senses the lower frequency of the calcium dynamics. Here, we wanted to explore how different PDE4 concentrations and isoform types regulate downstream signaling dynamics of oscillatory cAMP signaling.

**Figure 6. The influence of PDE4 concentration on oscillatory cAMP signaling as predicted by the computational model.** A) Dynamic control of oscillatory cAMP pulses is dependent on the concentration of total PDE4 present. Relative proportions of long, short and supershort PDE4 isoforms were kept constant. B-D) Lower total PDE4 concentrations induced higher levels of activated PKA, Epac, and ERK. PKA, Epac and ERK reflect the species  $PKA_{cat,1}$ ,  $Epac_{ON}$ , and  $ERK_{dimer}$ , respectively. Simulations were run for 1500 s considering estimated hippocampal PDE4 isoform proportions.

Similar as seen for a single cAMP pulse, the concentration of total PDE4 regulates oscillatory cAMP signaling and activation of downstream effectors (Fig 5 and 6). Higher (3.0 μM) and lower (0.3 μM) PDE4 concentrations resulted, respectively, in a faster and slower degradation of oscillatory cAMP (Fig 6A). Accordingly, activation of the effectors PKA ( $PKA_{cat,1}$ ), Epac ( $Epac_{ON}$ ) and ERK ( $ERK_{dimer}$ ) was similarly changed and these effects were highly non-linear (Fig. 6B-D). Interestingly, and in contrast to a single pulse of cAMP, the isoform type or the relative proportion greatly influenced the rate of cAMP degradation in the simulated settings. More specifically, when keeping the total PDE4 concentration equal at 1 μM

but varying the type of isoform, Fig. 7 shows that the long and short isoforms maintain an oscillatory cAMP profile (albeit with a higher initial peak for the short isoform with respect to the long isoform, Fig. 7A), while the supershort isoform is not able to degrade the cyclic cAMP input at a sufficient rate, leading to a fast accumulation of cAMP (Fig. 7A insert). Also downstream signaling is distinct when only a specific PDE4 isoform type is present. For the short and long isoform, the steady state levels of activated PKA and Epac oscillate around  $0.05 \mu\text{M}$  and  $0.025 \mu\text{M}$  respectively, whereas for the supershort isoform, the steady state Epac and PKA levels are almost 10- and 5-fold higher ( $0.24 \mu\text{M}$  and  $0.27 \mu\text{M}$ , Fig. 7B-C). A gradual increase in cAMP concentration followed by a sustained input resulted in similar findings to the cyclic cAMP input, i.e. the long and short isoforms maintain a stable cAMP profile, while the supershort isoform is not able to degrade the sustained cAMP input at a sufficient rate, leading to a fast accumulation of cAMP (see Supplementary Figure S2). As such, these results nicely correspond to the findings of the Conti laboratory in which sustained adenylyl cyclase activation as been shown to result in a transient increase in the intracellular cAMP concentration after which the intracellular cAMP concentrations reach a steady state level (for long isoform activation through PKA) (Rich et al., 2007). These simulations indicate that cAMP signaling is not effectively controlled in the presence of supershort PDE4 isoforms alone, suggesting that additional biological mechanisms would have to be employed to prevent cAMP levels from rising uncontrollably.

**Figure 7. PDE4 isoform types differentially regulate oscillatory cAMP signaling.** The effect of PDE4 isoform type on oscillatory cAMP signaling was simulated by including a single PDE4 isoform type only at a concentration of 1  $\mu\text{M}$ . A) Dynamic control of oscillatory cAMP signaling is distinct for different PDE4 isoform types. Presence of supershort PDE4 isoforms only leads to profound accumulation of cAMP (insert). When only short or long PDE4 isoforms are present, cAMP levels can be stabilized in a concentration range after an initial peak. B-C) Similar to the effect on oscillatory cAMP control, PKA and Epac are most profoundly activated when only supershort PDE4 isoforms are present. In case only short PDE4 isoforms are present, an initial increase can be observed after which activation levels stabilize. D) Similar to PKA and Epac activation, ERK activation increased mainly when only supershort isoforms were present. Presence of only short PDE4 isoforms led to a higher ERK activation compared to long PDE4 isoforms only. PKA, Epac and ERK reflect the species  $\text{PKA}_{\text{cat},1}$ ,  $\text{Epac}_{\text{ON}}$ , and  $\text{ERK}_{\text{dimer}}$ , respectively. Simulations were run for 1500 s with oscillatory cAMP input (0.3  $\mu\text{M}$ ).

### PDE4 activity changes over time in an isoform-specific manner

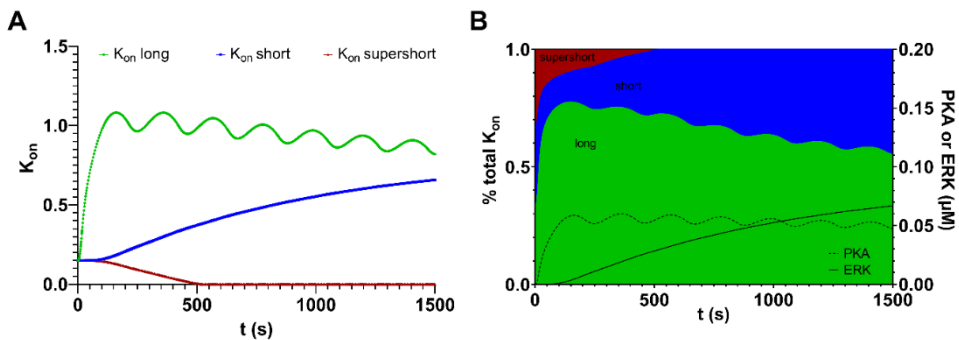

To understand why the type of PDE4 isoform only has an important impact for cyclic cAMP pulses and not for a single cAMP pulse in the computational model, we looked in detail at Equation 1 in Table 1 (Material and Methods). The activity, i.e.

the degradation rate, of the PDE4 isoform types is differentially affected upon phosphorylation events by activated PKA and ERK. As PKA and ERK themselves are dynamically regulated over time (Fig 7B,D), we next sought to investigate how the degradation rates for the different PDE4 isoform types change over time as a response to oscillatory cAMP signaling.

For a single cAMP pulse, the degradation rates overlap for all isoforms types (Figure 5E) which can be explained by the fact that the elevations in activated PKA and ERK concentrations are small (Figure 5B-D) resulting in no or negligible differences between the enzymatic activity of different PDE4 isoforms. In contrast, for cyclic cAMP pulses there is a continuous generation of activated ERK and PKA, leading to higher overall degradation rates by means of biological feedbacks loops impacting upon PDE4 activity (Fig 6A). For the long isoform, of which the activity is regulated by both PKA and ERK, the activation rate is higher than the inhibition rate, which reflects the  $V_{max}$  settings (i.e. 21.76 for activation, -2 for inhibition), resulting in net increased activation (Fig 8A and Supplemental Figure S1). In other words, the activation of the long isoform by PKA keeps the PKA concentration under control, since a higher degradation rate of cAMP results in less PKA formation (a negative feedback loop), resulting in a compensatory  $k_{12_{on,PDE}}$  rate. The short isoform is activated by ERK. Since the activation of ERK is slower than of PKA (Fig 6B,D), the increase in  $k_{on,short}$  (i.e.  $k_{on,PDE} + k_{23_{on,PDE}}$ ) is slower than the increase of  $k_{on,long}$  (i.e.  $k_{on,PDE} + k_{12_{on,PDE}} + k_{13_{on,PDE}}$ ) and overall a lower activation rate is reached for short PDE4 compared to long PDE4. Consequently, the cAMP has a larger initial peak when only the short isoform is present in comparison to when all (Fig 6A), or only the long isoform (Fig 7A) is present.

The supershort isoform is inhibited by ERK, which represents a positive feedback loop. More specifically, a high ERK concentration inhibits the degradation of cAMP by long and supershort PDE4 forms, leading to downstream activation of ERK. Consequently, in the simulations of cyclic cAMP input with only the supershort

isoform present, the  $k_{on}^{supershort}$  (i.e.  $k_{on,PDE} + k33_{on,PDE}$ ) rate flattens out already after 500s (Fig 8A-B), implying that there is no degradation of cAMP anymore (all PDE4 supershort isoforms are inhibited) resulting in a massive build-up of the cAMP concentration (Fig. 7A). These simulations show that, in cases where only the supershort isoform is present, other mechanisms should be activated to limit the cAMP concentration increase, and in particular mechanisms that limit the activation of the ERK pathway or increase the cAMP degradation in an PDE4-independent mechanism.

**Figure 8. Degradation rates of cAMP by PDE4 long, short, and supershort isoforms change differentially over time.** The degradation rates of long ( $K_{on}^{long}$ ), short ( $K_{on}^{short}$ ) and supershort ( $K_{on}^{supershort}$ ) forms are shown in green, blue and red, respectively. Degradation rates per PDE4 isoform are dependent on the baseline degradation rate and modulation by PKA and/or ERK and are calculated based on Tables 1 and Table 2 ( $K_{on}^{long} = k_{on,PDE} + k12_{on,PDE} + k13_{on,PDE}$ ;  $K_{on}^{short} = k_{on,PDE} + k22_{on,PDE} + k23_{on,PDE}$ ;  $K_{on}^{supershort} = k_{on,PDE} + k32_{on,PDE} + k33_{on,PDE}$ ). A) Changes in absolute degradation rates per PDE4 isoform type are plotted over time. B) The contribution of different PDE4 isoform types to the total degradation changes over time. Changes in degradation rate correspond to changes in PKA and ERK levels as shown by the dashed (PKA) and solid (ERK) black line. PKA and ERK reflect the species  $PKA_{cat,1}$  and  $ERK_{dimer}$ , respectively. Simulations were run for 1500 s considering estimated hippocampal PDE4 isoform proportions (total 1  $\mu$ M) and oscillatory cAMP input (0.3  $\mu$ M).

The degradation rates of long and supershort PDE4 isoforms start to go down once ERK becomes activated while short forms are activated (Fig 8A-B). This implies that, in case ERK is already activated and PDE4 long and supershort forms

are thus initially inhibited before cAMP synthesis is started, PDE4-mediated cAMP degradation could be diminished. This means that preceding ERK activation, by inhibition of long and supershort PDE4, could have 'permissive and facilitating' actions on cAMP signaling.

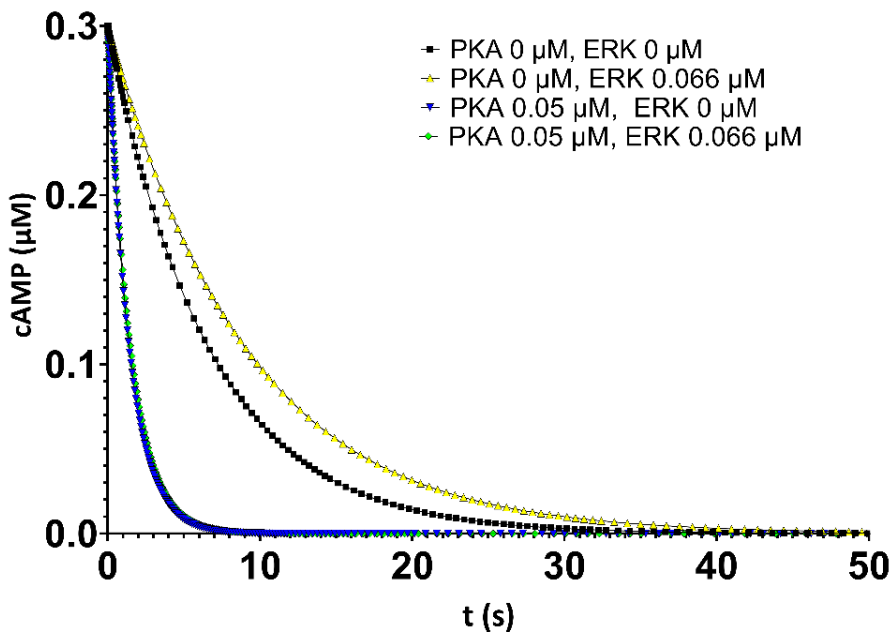

To investigate the influence of  $V_{max}$  parameter values on the model outcome, we performed a sensitivity analysis in which we varied the  $V_{max}$  values  $\pm 10\%$  and looked at the average and maximum cAMP value over 1500 seconds (see Supplementary Figure S3). As can be appreciated from these results, the sensitivity of the model is similar for all  $V_{max}$  values, with the highest for  $kon12PDE$  which captures the effect of the long isoform phosphorylation by PKA. In this respect, the sensitivity analysis is in line with the other reported results that highlight the important effect of the long isoform. Importantly, we highlight here that due to the scarcity of quantitative data, the baseline  $V_{max}$  values are based on measures in different cell types using different assays.

### **Initial PKA and ERK concentrations influence PDE4-mediated cAMP degradation**

Despite the large influence of PKA and ERK on PDE4-mediated cAMP degradation, our prior simulations did not take into account the initial presence of PKA and/or ERK and may therefore not fully represent the biological situation in which these species may modulate PDE4 activity already before cAMP is synthesized. Therefore, we also explored the influence of the activated PKA and ERK concentration on PDE4-mediated cAMP degradation by using non-zero initial concentrations (0.05 and 0.066  $\mu\text{M}$ , respectively) based on their final values in the simulations shown in Figure 6B and -D. The following simulations were run using a single pulse only, since cyclic pulses lead to continuous degradation and production which overrules the effect of different initial PKA and ERK conditions.

Figure 9 shows the degradation dynamics of a single 0.3  $\mu\text{M}$  cAMP pulse for different initial concentrations of PKA and ERK. Similar to above, these results

indicate that the initial PKA concentration has an important influence on cAMP degradation by increasing the activity of long PDE4 isoforms and overruling a potential influence of initial ERK concentrations (i.e. note that the curves of the green diamonds and blue triangles overlap in Figure 9). In case no PKA is initially present, non-zero initial concentrations of ERK also influence cAMP degradation by inhibiting long and supershort PDE4 isoforms while activating short PDE4 isoforms. Depending on the intracellular distribution of the different PDE4 isoform types and their relative proportions, these initial PKA and ERK concentrations may give rise to specific intracellular cAMP gradients by distinctly influencing PDE4 activity.

**Figure 9. The initial concentrations of PKA and ERK influence degradation of a single cAMP pulse.** Elevated initial PKA levels lead to quicker degradation of a single 0.3  $\mu\text{M}$  cAMP pulse (blue triangles), while increased initial ERK levels diminish degradation (yellow triangles) compared to the default simulation in which PKA and ERK are initially absent (black squares). When both PKA and ERK are initially present, PKA overrules the effect of ERK indicating that PKA, by activating long PDE4 isoforms, has a major influence on PDE4-mediated cAMP degradation (green diamonds). PKA and ERK reflect the species  $\text{PKA}_{\text{cat},1}$  and  $\text{ERK}_{\text{dimer}}$ , respectively. Simulations were run considering estimated hippocampal PDE4 isoform proportions (total 1  $\mu\text{M}$ ) with a single cAMP pulse input (0.3  $\mu\text{M}$ ).

**Figure 10. Effects of isoform-type specific PDE4 inhibition on cAMP and downstream signaling.** The effect of isoform-specific PDE4 inhibition on cAMP signaling was tested while considering the relative proportions of isoform types measured in the hippocampus (panels A, C, E and G) or considering equal expression proportions of the different PDE4 isoform types (panels B, D, F and H) for a cyclic input of cAMP. Inhibition of long PDE4 isoforms (green lines) produced the largest elevations in cAMP (A-B), PKA (C-D), Epac (E-F), and ERK levels (G-H) irrespective of the proportion of isoform types. Inhibition of short forms (blue lines) led to higher levels of cAMP and downstream molecules than inhibition of supershort forms (red lines) when considering equal isoform type proportions (B,D,F,H) but not in case of hippocampal proportions (A,C,E,G) indicating relative proportions determine the functional importance of isoform types. PKA, Epac and ERK reflect the species  $PKA_{cat,1}$ ,  $Epac_{CON}$ , and  $ERK_{dimer,r}$  respectively. Simulations were run for 1500 s with oscillatory cAMP input ( $0.3 \mu M$ ).

## **Inhibition of PDE4 long isoforms has the most profound effect on cAMP signaling**

Based on the observations that cAMP signaling is best kept under control when long PDE4 isoforms are present (Fig 7), long isoforms contribute largely to the total PDE4-mediated cAMP degradation (Fig 8), and the dominant effect of PKA over ERK in modulating PDE4 activity by acting on long PDE4 forms specifically (Fig 9), we sought to investigate whether inhibition of long PDE4 isoforms specifically impacts cAMP signaling most profoundly compared to inhibition of the other isoform types.

Inhibition of single PDE4 isoform types was simulated by setting this isoform to zero while leaving the other two types unaffected. In prior simulations we have used the relative proportions of long, short, and supershort PDE4 isoforms based on those measured in the hippocampus as an example of tissue-specific expression, i.e. 0.7 long, 0.11 short, 0.19 supershort. Since long PDE4 isoforms comprised 70% of the total in this tissue, the observations that long PDE4 isoforms exert a large control on cAMP signaling may have been biased by the fact that these long forms are most abundantly present. To control for this potential bias we also simulated the inhibition of an isoform type while keeping the remaining forms in equal proportions, i.e. one isoform is set to zero and the other isoforms are both present at 0.5  $\mu\text{M}$  concentration in order to keep the total PDE4 concentration constant at 1  $\mu\text{M}$ .

Figure 10 visualizes the effect of PDE4 isoform type inhibition on cAMP signaling considering both the hippocampal proportion of isoform types as well as equal proportions. Irrespective of the proportions considered, inhibition of long PDE4 forms led, compared to inhibition of short or supershort isoforms, to higher levels of cAMP (green curve, Fig 10A,B), PKA (green curve, Fig 10C,D), Epac (green curve, Fig 10E,F), and ERK signaling (green curve, Fig 10G,H). Inhibition of short isoforms differed from the inhibition of supershort forms only when considering equal proportion of isoform types (Fig 10B,D,F,H) which demonstrates that unequal abundance of PDE4 isoform types (e.g. in the case of the hippocampus) influences the functional importance of a particular isoform type.

## DISCUSSION

Various intra- and extracellular stimuli all induce the synthesis of cAMP but eventually evoke distinct cellular effects. This 'repurposing' of the same signaling machinery by controlling its dynamics is beneficial from an evolutionary perspective compared to developing separate pathways for each stimulus, receptor or response (Purvis and Lahav, 2013). Accordingly, by means of compartmentalization and multiple (dynamic) feedback mechanisms, cAMP can convey signals from multiple different sources to induce distinct responses. By degrading cAMP, PDE4 enzymes exert profound control over cAMP signaling dynamics. Specifically, PDE4 enzymes consist of multiple isoform types of which the enzyme activity is dynamically regulated in a feedback-based manner in response to downstream cAMP signaling. Here, we constructed a computational model to explore the role of PDE4 and its different isoforms in the control of cAMP dynamics.

Based on our model, we explored the effects of different concentrations cAMP and PDE4 on activation of the downstream cAMP-PKA and cAMP-Epac pathways. It was identified that PKA activation was mainly influenced by the concentration of cAMP, whilst Epac activation was more sensitive to the amount of PDE4 present. Moreover, simulations using different total PDE4 concentrations caused substantial changes in PKA and Epac activation dynamics by changing time to peak values, whilst simulation using different cAMP concentrations did not. Changes in PDE4 concentration led to non-linear changes in the dynamics of cAMP and downstream effectors, which provides an estimation of the magnitude of effect of experimentally observed changes in PDE4 expression. For example, the 1.5-4.0 fold increases in PDE4 at the mRNA, protein, and enzyme activity level that have been reported in physiological and disease-associated conditions do affect cAMP and downstream signaling based on our model (Levallet et al., 2007; Paes et al., 2020; Peter et al., 2007).

In light of investigating the effect of PKA- and ERK-based feedback on PDE4 isoform activity, our simulations indicated that oscillatory cAMP signaling, as opposed to single cAMP input pulses, is necessary to induce downstream effector activation that can influence PDE4 isoform activity. As the change in enzyme activity upon phosphorylation by PKA and/or ERK is PDE4 isoform-specific, we examined how oscillatory cAMP signaling affects the activity of these PDE4 isoform types. The results indicated long PDE4 isoforms exert the largest control on dynamics of cAMP and downstream effector signaling (Fig. 7) and that long PDE4 isoforms contribute most to total PDE4-mediated cAMP degradation (Fig 8). These long-dominant effects may have been biased by the fact that we considered PDE4 isoform proportions based on measurements in rat hippocampal tissue, in which long forms were predominantly (i.e. 70%) present. However, simulations in which each of the PDE4 isoform type were present in equal amount and were separately inhibited, long forms also exhibited the largest impact on cAMP and downstream signaling dynamics (Fig 10). This seemingly importance of long PDE4 forms is supported by the fact that the four PDE4 genes (*PDE4A-D*) encode more long isoforms than short and supershort isoforms (Paes et al., 2021), which may imply that long forms are involved in a broader array of cellular functions. Indeed, these various long PDE4 isoforms are known to localize to specific intracellular compartments owing to their unique N-terminus amino acid stretches to engage in specific protein-protein interactions (Houslay, 2010; Paes et al., 2021). As such, long PDE4 isoforms can control cAMP signaling in a precisely located and efficient manner as their activity can be quickly increased upon phosphorylation by PKA.

In contrast to long forms, supershort PDE4 forms were found to inadequately control oscillatory cAMP signaling (Fig 7). These isoforms cannot be phosphorylated, and activated, by PKA, but are only affected by ERK phosphorylation. However, phosphorylation by ERK actually decreases enzyme activity of supershort PDE4 while modestly increasing the activity of short PDE4 forms. Thus, phosphorylation-based

feedback mechanisms appear insufficient in increasing supershort PDE4 isoform activity. This may imply that cAMP levels could become uncontrollable in compartments where only supershort PDE4 forms are present. However, early studies have reported the transcription-based upregulation of (super)short PDE4 in response to cAMP signaling activation as an alternative feedback mechanism (Conti, 2000; Liu et al., 2000; Swinnen et al., 1991b). Moreover, (super)short forms have been shown to localize throughout the cytosol where they may control cAMP signaling globally compared to cAMP control by long PDE4 forms in specific locations (Bolger et al., 1997; Cheung et al., 2007; Huston et al., 1997).

The results of this study, which indicate the effects of PDE4 isoform types on cAMP signaling dynamics, should be interpreted in the light of the following assumptions and limitations. Firstly and most importantly, The model simulations predict that all cAMP is degraded in approximately 15 seconds (single cAMP pulse), which differs from the reported cAMP measurements in live cells (i.e. 100-300 seconds (Violin et al., 2008)). Although this discrepancy may be cell-dependent, we hypothesize that this might be due to the ODE formalism we are using as such do not fully account for the spatial regulation of cAMP signaling via cAMP compartmentalization and local subcellular cAMP gradients. More specifically, precise subcellular localization of PDE isoforms is proposed to be important for shaping cAMP gradients (Barnes et al., 2005; Feinstein et al., 2012; Xin et al., 2015). Here, we provide a very rough approximation of how different isoforms of a certain PDE4 subtype may be proportionally expressed in (parts of) an organ. As such, our approximation of the ratio of different PDE4 isoform categories by means of a Western blot of just the PDE4D subtype does not reflect or provide information on the expression of all PDE4 subtypes and isoforms in specific cell types and their localization within these cells. Interestingly, of the 21 reported human PDE4 isoforms, 15 are long (70%), 2 are short (10%), and 4 are supershort isoforms (20%) which reflects very similar proportions as reported for PDE4D isoforms here (Paes et al.,

2021). As soon as isoform-specific intracellular expression patterns are determined, these details can be included in future models. In addition, local production by ACs, cAMP buffering (by e.g. PKA), physical barriers (i.e. the cytoskeleton), export by multidrug resistance proteins and cell shape are also believed to contribute to cAMP compartmentalization (Saucerman et al., 2014). Importantly, recent insights indicated that cAMP is primarily buffered by PKA regulatory subunit condensates and that PDEs effectively reduce cAMP signaling in highly localized, nanometer-sized compartments (Bock et al., 2020; Jackson, 2020; Zhang et al., 2020). Also, A-kinase anchoring proteins (AKAPs) have the ability to anchor PKA, Epac and PDE4 to specific subcellular locations, to form local signaling complexes with high signaling specificity and efficacy (Dema et al., 2015; Omar and Scott, 2020). By tethering PKA to specific subcellular locations, it can specifically activate effector proteins in its vicinity. Besides, AKAPs can also directly bind effector proteins, to spatially and temporally influence the signal transduction (Dema et al., 2015; Omar and Scott, 2020). AKAPs are thus important players in establishing compartmentalized cAMP signaling by contributing to the subcellular localization of signaling components, but it is not yet completely understood how the intracellular positioning of cAMP effector proteins (i.e. PDE4, Epac, PKA) by AKAPs shapes cellular cAMP signaling.

Secondly, considering the short time scales that we model, we assume a constant amount of protein, thus ignoring potential production and degradation processes. For example, the transcriptional upregulation of (super)short PDE4 as feedback mechanism may take longer than 1500 s as simulated here, but could be implicated in future models. as well as transcriptional or epigenetic regulation (Paes et al., 2020; Paes et al., 2021; Tilley and Maurice, 2005). For example, the transcriptional upregulation of (super)short PDE4 as feedback mechanism may take longer than 1500 s as simulated here, but could be implicated in future models. Earlier studies reported large increases in (super)short transcripts, but these were observed after a period of multiple hours (Swinnen et al., 1989; Swinnen et al., 1991a).

Because of this difference in time frames and the difficulty of translating cAMP increases to downstream transcriptional upregulation, we opted to not include transcription-regulated feedback in this model yet. Thirdly, this study focuses on PDE4, whereas other cAMP degrading PDEs also play an important role in the spatiotemporal dynamics of cAMP signaling. Similarly, the PDE4 activity can be modulated through a wide variety of post-translational modifications and interactions with partner proteins (Paes et al., 2021), which are not all captured in the current model. For example, the effect of phosphatases, which would remove phosphorylation of PDE4 or undo effects of PKA in Raf-1 expressing cells on phosphorylation of Raf1 and its downstream signaling to ERK (Stork and Schmitt, 2002), providing yet other cell-specific routes for cAMP and ERK signaling pathways to interact, could be incorporated in future work. Finally, the parameter values of the model (e.g. proportional/relative concentrations of included signaling molecules and the way they influence each other) are highly cell type-, context-, and compartment-specific (Dodge-Kafka et al., 2005; Dugan et al., 1999; Stork and Schmitt, 2002). Future work should focus on acquiring these cell-type and context-specific experimental data (e.g. using next-generation cAMP-sensing techniques (Bock et al., 2020)) in order to better calibrate the computational models (including, if necessary, stochastic simulation techniques such as reported in {Jędrzejewska-Szmek, 2017 #908}) and simulate these dedicated scenarios.

The current study pointed out that different PDE4 isoforms distinctly regulate cAMP and downstream signaling dynamics and that these isoform-specific differences should be considered in future computational and experimental work on PDE4/cAMP signaling. Computational follow-up studies could focus on PDE4/cAMP signaling in specific cellular compartments or cell types by adapting the model presented here. Moreover, this model can provide insights in PDE4 drug design by simulating how PDE4 inhibitors, with different affinities to the different isoform types, impact overall cAMP signaling. Experimentally, future computational work should

validate the influence of specific PDE4 isoforms on cell-type specific cAMP-regulated processes by using, for example, RNA silencing or (epi)genetic editing.

## **ACKNOWLEDGMENTS**

We thank Zeynep Karagöz for independently confirming our simulation results. AC gratefully acknowledges the financial support of the Dutch province of Limburg in the LINK (FCL67723) (“Limburg INvesteert in haar Kenniseconomie”) knowledge economy project and a VENI grant (number 15075). This work was supported by Alzheimer Nederland [Grant WE.03-2016-07]. TV and JP have a proprietary interest in selective PDE4D inhibitors for the treatment of demyelinating disorders. JP has a proprietary interest in the PDE4 inhibitor roflumilast for the treatment of cognitive impairment as well as PDE4D inhibitors for the treatment of Alzheimer’s disease.

## **CONTRIBUTIONS**

DP, SH, and AC developed the computational model. DP, SH and AC analyzed its results. DP, TV, JP, and AC contributed to the design and conception of the study. DP, SH, and AC drafted the manuscript. DP, SH, DvdH, TV, and JP contributed to manuscript revision, read, and approved the submitted version.

## SUPPLEMENTARY MATERIAL

**Figure S1. Changes in degradation rates  $k_{12on,PDE}$ ,  $k_{13on,PDE}$ ,  $k_{23on,PDE}$ , and  $k_{33on,PDE}$  over time.**  $k_{12on,PDE}$  reflects the activating effect of phosphorylation by PKA on long PDE4 isoform activity (top left).  $k_{13on,PDE}$  and  $k_{33on,PDE}$  reflect the inhibiting effects of phosphorylation by ERK on long and supershort PDE4 isoform activity, respectively (top right and bottom right).  $k_{23on,PDE}$  reflects the activating effect of phosphorylation by ERK on short PDE4 isoform activity (bottom left). Note the differences in y-axes. Simulations were run for 1500 s considering estimated hippocampal PDE4 isoform proportions (total 1  $\mu$ M) and oscillatory cAMP input (0.3  $\mu$ M).

**Figure S2. PDE4 isoform types differentially regulate sustained cAMP signaling.** The effect of PDE4 isoform type on sustained cAMP signaling was simulated by including a single PDE4 isoform type only at a concentration of 1  $\mu\text{M}$ . A) Dynamic control of sustained cAMP signaling is distinct for different PDE4 isoform types. Presence of supershort PDE4 isoforms only leads to profound accumulation of cAMP (insert). When only short or long PDE4 isoforms are present, cAMP levels can be stabilized in a concentration range after an initial peak. B-C) PKA and Epac are most profoundly activated when only supershort PDE4 isoforms are present. In case only short PDE4 isoforms are present, an initial increase can be observed after which activation levels stabilize. D) Similar to PKA and Epac activation, ERK activation increased mainly when only supershort isoforms were present. Presence of only short PDE4 isoforms led to a higher ERK activation compared to long PDE4 isoforms only. PKA, Epac and ERK reflect the species PKAc<sub>at,1</sub>, EpacON, and ERKdimer, respectively. Simulations were run for 1500 s with gradual increase and then constant cAMP input (0.3  $\mu\text{M}$ ).

**Figure S3. Local sensitivity analysis of the cAMP model.** Parameter sensitivity values on the y-axis indicate how a 10% increase (light orange) or decrease (dark orange) in each parameter [vmax parameter values, see also Table 2] affects the average (left) and maximum (right) cAMP value over 1500 seconds for a oscillatory input of cAMP and considering estimated hippocampal PDE4 isoform proportions (total 1  $\mu$ M).

### Estimation of proportional PDE4 isoform type expression in rat hippocampus tissue

Sample preparation and western blotting methodology was performed as previously described (Argyrousi et al., 2020; Nelissen et al., 2017). Briefly, hippocampal tissue of a 4-month-old male Wistar rat was used. Approximately 20 mg of the left hippocampus was homogenized in 400  $\mu$ l lysis buffer (100 mM Tris-HCl, 200 mM NaCl, 1 mM EDTA, 2 mM DTT, 0.05% Triton, 1 tablet complete protease inhibitor mix/20 ml buffer (Roche, Vilvoorde, Belgium), 1 tablet PhosSTOP phosphatase inhibitor cocktail/10 ml buffer (Roche) using a mini-Bead-Beater (BioSpec products, Bartlesville, OK, USA). Samples were homogenized three times for 30 s with 5 min cooling on ice between runs. After 30 min cooling on ice, samples were centrifuged at 16,000  $\times$  g for 20 min. (4  $^{\circ}$ C), and the supernatant was divided into aliquots and stored at -80  $^{\circ}$ C until further use. Protein concentrations were determined with the Bio-Rad DC<sup>TM</sup> protein assay (Bio-Rad Laboratories, Inc.).

Brain homogenate (total protein input, 20  $\mu$ g) was resolved in 10% SDS polyacrylamide gel electrophoresis and then transferred onto nitrocellulose membranes (Bio-Rad Laboratories). The membranes were blocked (50% Odyssey blocking buffer in PBS; Li-Cor, Lincoln, NE) for one hour at room temperature, followed by overnight incubation with the primary antibodies at 4°C. The primary antibodies consisted of rabbit anti-PDE4D (1:500, ab14613; Abcam) and mouse anti-GAPDH (1:1,000,000, #10R-G109A; Fitzgerald Industries, Acton, MA) as loading control. Membranes were subsequently incubated with secondary antibodies for one hour at room temperature: goat anti-rabbit IRDye 800 (1:10,000; Li-Cor) and donkey anti-mouse IRDye 680 (1:10,000; Li-Cor). Membranes were visualised using the Odyssey Infrared Imaging System (Li-Cor), and protein bands were quantified using ImageJ by means of densitometry (National Institutes of Health, Bethesda, MD). Protein bands of ~55 kDa were considered to be supershort PDE4D isoforms, bands of ~65 kDa were considered to be PDE4D short isoforms and band >75 kDa were considered to be long PDE4D isoforms (Supplemental Figure 4).

**Figure S4. Western blot image of rat hippocampal tissue (right column) stained for PDE4D.** Protein bands of ~55 kDa were considered to be supershort PDE4D isoforms, bands of ~65 kDa were considered to be PDE4D short isoforms and band >75 kDa were considered to be long PDE4D isoforms.

Paes et al. (2021) *Neuropharmacology*. Feb 15;184:108414.  
doi: [10.1016/j.neuropharm.2020.108414](https://doi.org/10.1016/j.neuropharm.2020.108414)

## **ABSTRACT**

Phosphodiesterases (PDE) are the only enzymes that degrade cAMP and cGMP which are second messengers crucial to memory consolidation. Different PDE inhibitors have been developed and tested for their memory-enhancing potential, but the occurrence of side effects has hampered clinical progression. As separate inhibition of the PDE2 and PDE4 enzyme family has been shown to enhance memory, we investigated whether concurrent treatment with a PDE2 and PDE4 inhibitor can have synergistic effects on memory consolidation processes. We found that combined administration of PF-999 (PDE2 inhibitor) and roflumilast (PDE4 inhibitor) increases the phosphorylation of the AMPA receptor subunit GluR1 and induces CRE-mediated gene expression. Moreover, when combined sub-effective and effective doses of PF-999 and roflumilast were administered after learning, time-dependent forgetting was abolished in an object location memory task. Pharmacokinetic assessment indicated that combined treatment does not alter exposure of the individual compounds. Taken together, these findings suggest that combined PDE2 and PDE4 inhibition has synergistic effects on memory consolidation processes at sub-effective doses, which could therefore provide a therapeutic strategy with an improved safety profile.

## INTRODUCTION

Cyclic nucleotides are second messengers that convey extracellular signals to adaptive changes within the cell. In the central nervous system, cyclic adenosine monophosphate (cAMP) and cyclic guanosine monophosphate (cGMP) have been suggested to play a crucial role in neuronal signal transduction and memory consolidation processes. Downstream targets of cAMP and cGMP include protein kinases (e.g. PKA and PKG), nucleotide exchange factors (Epac1 and Epac2), popeye-domain containing proteins (POPDC) and cyclic nucleotide gated channels (CNGC). Via these downstream targets, cAMP and cGMP can modulate a multitude of processes involved in synaptic plasticity mechanisms like long-term potentiation (LTP). LTP takes place in two distinct phases: short-lasting early LTP (E-LTP) during which no gene transcription or translation is induced and enduring late LTP (L-LTP) which does involve gene expression and protein synthesis. As such, E-LTP consists of post-translational modifications (e.g. phosphorylation) by which the localization and functionality of proteins can be adapted. For example, phosphorylation of specific residues on the AMPA receptor subunit GluR1 induces receptor trafficking and conductivity changes which then facilitate synaptic plasticity (Lee, 2006). L-LTP involves transcription of plasticity genes regulated by the transcription factor CREB (Barco et al., 2002; Kida, 2012; Suzuki et al., 2011). Cyclic nucleotide levels modulate both E-LTP and L-LTP through activation of downstream effectors which can subsequently phosphorylate different substrates (e.g. CREB) and induce gene transcription.

Intracellular cyclic nucleotides are degraded exclusively by phosphodiesterases (PDE). The PDE enzyme family comprises 11 gene families (PDE1-11) that specifically target cAMP (PDE4, -7, -8), cGMP (PDE5, -6, -9) or have specificity to both (PDE1, -2, -3, -10, -11) (Bender and Beavo, 2006). Since PDEs are the sole enzymes regulating cyclic nucleotide levels, pharmacological inhibition of PDEs provides an approach to modulate cyclic nucleotide concentrations and

subsequently influence neuronal plasticity and memory processes. Accordingly, preclinical studies indicated that inhibition of different PDE subtypes can improve neuronal plasticity and memory functioning. Inhibition of PDE2, PDE4, PDE5, PDE9 and PDE10 has been demonstrated to enhance cognitive functioning, including memory, in rodent preclinical studies (reviewed in: (Heckman et al., 2017)). For example, treatment with the PDE2 inhibitor BAY60-7550 improves hippocampal long-term potentiation and object recognition memory in rats (Boess et al., 2004; Domek-Lopacinska and Strosznajder, 2008; Rutten et al., 2007). Chronic oral administration of this compound (0.3 mg/kg) improved memory in a transgenic AD mouse model (Sierksma et al., 2013). These studies indicate the therapeutic potential of PDE2 inhibition, but poor pharmacokinetic properties of BAY60-7550 make this molecule unsuitable for clinical development. Hence, efforts have been made to develop new, selective PDE2 inhibitors (reviewed in: (Gomez and Breitenbucher, 2013)). The PDE2 inhibitor PF-05180999 (PF-999) showed better pharmacokinetics but Phase I clinical trials (NCT01981486, NCT01429740 and NCT01981499) testing its use in schizophrenia and migraine were discontinued (Helal et al., 2017). Selective PDE4 inhibitors and their effect on plasticity and memory processes have been described more extensively. PDE4 inhibition by rolipram or FFPM restores memory performance in transgenic AD mice as well as models using natural ageing or streptozotocin to induce cognitive impairments (Gong et al., 2004; Guo et al., 2017; Kumar and Singh, 2017). PDE4 inhibitors have been reported to produce emetic side effects, which would hamper clinical use of non-selective PDE4 inhibitors (Vanmierlo et al., 2016). The PDE4 gene family contains four genes (PDE4A-D), each encoding multiple isoforms using different promoters and alternative splicing. Targeted inhibition of individual PDE4 genes or isoforms can also increase neuroplasticity and memory functioning (Li et al., 2011; Sierksma et al., 2014; Zhang et al., 2018; Zhang et al., 2017). Specific inhibition of PDE4D using the compound GEBR-7b (0.001 mg/kg, s.c.) improved spatial memory in APP<sup>swe</sup>/PS1<sup>dE9</sup> mice (Sierksma et al., 2014).

As PDE4D inhibition is thought to be underlying emetic side effects (Mori et al., 2010), approaches may be necessary to circumvent the occurrence of side effects. Similarly, as found upon PDE2 and PDE4 inhibition, object memory is improved by PDE5 inhibition using sildenafil, vardenafil or icariin (Jin et al., 2014; Prickaerts et al., 2002; Puzzo et al., 2008; Puzzo et al., 2009; Reneerkens et al., 2012; Zhang et al., 2013). In addition, PDE5 inhibition has protective actions against striatal degeneration through stimulation of neuronal survival pathways (Puerta et al., 2010). Two different PDE9 inhibitors (BAY-73-6691 and PF-04447943) were found to have enhancing effects in healthy rodents and disease models in a variety of cognitive behavioral tasks (Hutson et al., 2011; van der Staay et al., 2008; Verhoest et al., 2012) and inhibition of PDE10 by papaverine or PQ-10 improves memory functioning in MK-801 and scopolamine-deficit models and a mouse model of Huntington's disease (Giralt et al., 2013; Reneerkens et al., 2013).

Although the inhibition of PDE2, PDE4, PDE5, PDE9 and PDE10 shows potential to enhance cognitive function in preclinical studies, inconsistent effects are found in clinical studies investigating the memory-enhancing effects of PDE inhibitors (Heckman et al., 2015; Heckman et al., 2017). As of yet, no PDE inhibitor has been clinically approved to improve cognitive functioning which can be attributed to unacceptable side-effects (in the case of PDE4), or a lack of efficacy (e.g. (Schwam et al., 2014)). Hence, alternative therapeutic approaches utilizing PDE inhibition should be explored to enhance efficacy and improve the safety profile. More recently, combined administration of a PDE4 (roflumilast) and PDE5 (vardenafil) inhibitor at sub-effective doses was found to improve memory in transgenic AD mice (Gulisano et al., 2018). Since PDEs are localized to specific compartments within the cell (Baillie, 2009), more subtle inhibition of different 'PDE microdomains' may collectively still facilitate signal transduction and LTP to produce memory-enhancing effects.

In the human brain, and in particular in memory-associated brain regions, PDE2 and PDE4 make up a large proportion of PDE activity (Lakics et al., 2010). Both PDE2 and PDE4 can regulate pre- and postsynaptic processes, making them interesting targets to enhance plasticity (Fernandez-Fernandez et al., 2015; Liu et al., 2017; Polito et al., 2013). Based on their regional and intracellular expression and the fact that separate inhibition of PDE2 or PDE4 promotes memory formation, we sought to investigate whether combined inhibition of PDE2 and PDE4 yields additive or synergistic effects to improve the treatment's safety profile and efficacy. To study potential synergistic effects of inhibition, we tested the effect of PDE2 and PDE4 inhibitors on processes underlying synaptic plasticity and spatial memory performance, and we established a pharmacokinetic profile of combined treatment.

## **METHODS**

### **Animals**

All experimental procedures were approved by the local ethical committee of Maastricht University for animal experiments and met governmental guidelines. Two batches of twenty-four 3-4-month-old male Wistar rats (Charles River, Sulzfeld, Germany) were used (average body weight at the beginning of the study: 346 g (batch 1) and 357 g (batch 2). The animals were housed individually in standard cages on sawdust bedding in an air-conditioned room (about 20°C). They were kept under a reversed 12/12 h light/dark cycle (lights on from 20.00 to 08.00) and had free access to food and water. Rats were housed and tested in the same room. A radio, which was playing softly, provided background noise in the room. All testing was done between 10.00 and 18.00.

### **Materials**

PF-999 and roflumilast were supplied by Dart NeuroScience as a white powder. Methyl 2-hydroxyethyl cellulose (Tylose® MH300) and Tween80 (polyoxyethylenesorbitan monooleate) were purchased from Sigma-Aldrich Chemie bv (Steinheim, Germany). For behavioral and PK experiments compound dilutions were freshly prepared on every experimental day and were dissolved in 0.5% tylose solution (98% of the end volume) with 2% Tween80. P-GluR1 (S845) antibody was obtained from Cell Signaling Technology (#8084). GluR1 antibody was purchased from Millipore Sigma (MAB2263). IRDye® Secondary Antibodies were purchased from LI-COR Biosciences.

### **Vectors used in CRE-mediated transcription**

We generated a ratiometric CRE-mediated gene expression reporter. Nuclear localized mCherry expressed under the control of a tandem repeat of CREs and a nuclear localized GFP was inserted downstream of the neuron-specific promoter Synapsin I. These two reporters drove expression in opposite directions with a DNA

insulator sequence nestled between. The ratiometric expression cassette was then packaged into AAV8 virus which infected 100% of the neurons in culture. The level of mCherry in the nucleus, a read-out of CRE-mediated gene expression, was normalized by the GFP level, which indicates the reporter infection efficiency. Thus, the mCherry:GFP ratio reads out the specific level of CRE-mediated gene expression in each neuron.

### **Rat Brain Section Preparations and Treatments**

Male Sprague-Dawley rats (8–12 weeks old) were anesthetized by isoflurane. The brains were rapidly removed and placed in ice-cold, oxygenated Krebs-HCO<sub>3</sub> buffer (124 mM NaCl, 4 mM KCl, 26 mM NaHCO<sub>3</sub>, 1.5 mM CaCl<sub>2</sub>, 1.25 mM KH<sub>2</sub>PO<sub>4</sub>, 1.5 mM MgSO<sub>4</sub> and 10 mM D-glucose, pH 7.4). Coronal slices (350 μm) were prepared using a vibrating blade microtome, VT1200 (Leica Microsystems, Nussloch, Germany). Neocortical and striatal sections were punched out from the slices in ice-cold Krebs-HCO<sub>3</sub> buffer. Three sections were placed in one incubation chamber of BSK6-6 brain slice keeper (Scientific Systems Design Inc.) with 4 mL of fresh Krebs-HCO<sub>3</sub> buffer containing adenosine deaminase (10 μg/mL, Roche Diagnostics, Indianapolis, USA). The slices were preincubated at 30 °C under constant oxygenation with 95% O<sub>2</sub>/5% CO<sub>2</sub> for 30 min. The buffer was then replaced with fresh Krebs-HCO<sub>3</sub> buffer without adenosine deaminase after 30 min of pre-incubation. Slices were treated with Krebs-HCO<sub>3</sub> buffer containing either vehicle (0.1% DMSO) or compound(s) for 30 min at 30 °C under constant oxygenation. To terminate the stimulation, each single slice was transferred to microcentrifuge tube, flashed frozen in liquid nitrogen and stored at -80 °C.

### **Immunoblotting**

Frozen tissue samples were sonicated in cell extraction buffer (LT FNN0011, Thermo Fisher Scientific, Carlsbad, US) containing complete protease inhibitor cocktail (Roche Diagnostics, Indianapolis, USA) and phosphatase inhibitor cocktail 1

and 2 (Sigma-Aldrich Corp., St. Louis, USA). The homogenate was centrifuged at 10,000×g for 15 min at 4 °C. Protein concentration in the supernatant was determined by the BCA using bovine serum albumin as standard protein assay method (Pierce, Rockford, IL, USA). Equal amount of protein samples were denatured in NuPAGE LDS sample buffer supplemented with NuPAGE Sample Reducing Agent, incubated at 75°C for 10 min, resolved by Bolt 10 % Bis-Tris Plus gels (Thermo Fisher Scientific, Carlsbad, US) transferred onto PVDF membrane subjected to immunoblot analysis with iBind™ Flex Fluorescent Detection kit. The membranes were immunoblotted using specific antibodies using Odyssey fluorescence detection system. Antibody bindings were revealed by incubation with IRDye 680RD donkey anti-mouse and IRDye 800CW Donkey anti-Rabbit secondary antibodies and imaged with Odyssey CLx near-infrared fluorescence imaging system. Images were processed and band intensity were quantified using Image Studio software (Licor-Odyssey, Lincoln, USA). For each experiment, values obtained for treated slices were calculated relative to the value for the control slices. Normalized data from multiple experiments were averaged and statistical analysis was carried out as described in the figure legends.

### **Cell culture and transfection**

Primary cortical cultures were prepared from E18 C57Bl/6 mice (Jackson Laboratories, Bar Harbor, ME, USA). Cortical tissue was dissociated using the Neural Tissue Dissociation Kit and the gentleMACS™ Octo Dissociator (Miltenyi Biotec, Auburn, CA, USA) as per manufacturer's instructions. Neurons were plated in BioCoat PDL-coated 96-well plates (Becton Dickinson, Franklin Lakes, NJ, USA) and maintained in Neurobasal medium (Thermo Fisher Scientific, Waltham, MA, USA) supplemented with MACS® NeuroBrew® -21 (Miltenyi Biotec, Auburn, CA, USA). Neurons were infected on DIV7 and experiments were performed on DIV9 or DIV10. Cultures were fixed in 4% PFA after overnight stimulation (18 hrs), immunostained

with an anti-Maps2 Ab (HM-2; Sigma Aldrich, St. Louis, MO) and anti-mouse Alexa-647 secondary antibody, and nuclei stained with Hoechst 33342 (Thermo Fisher Scientific, Waltham, MA, USA). We measured Hoechst, GFP, mCherry and Map2 on a Cell InSight high content imager (Thermo Fisher Scientific, Waltham, MA, USA). Automated algorithms identified the Hoechst-stained nuclei and with that mask, average pixel intensities for the GFP and mCherry channels were determined.

### **Object location task**

The object location test (OLT) was performed as described elsewhere using an identical apparatus and objects as those described previously (Akkerman et al., 2012a). Briefly, the effect of PF-999 and roflumilast on the consolidation processes of long-term memory was investigated using a 24 h interval between the OLT learning- and test-trials (T1 and T2, respectively). In the first two weeks, the animals were handled daily and were allowed to get accustomed to the test setup in two days, i.e. they were allowed to explore the apparatus (without any objects) twice for 3 min each day. Then the rats were adapted to the testing routine until they showed a stable discrimination performance, i.e. a good discrimination at 1 h interval and no discrimination at 24 h interval (data not shown). After this, the experiments were performed in which PF-999 and roflumilast were tested. PF-999 and roflumilast were tested at 0.03, 0.1 and 0.3 mg/kg and were administered p.o. (2 ml/kg), 3 h after T1 to investigate the effects on late memory consolidation. More specifically, dose-response curves were constructed for each of the compounds using the first batch of animals and subsequently the highest ineffective doses were combined to test their effectiveness on memory consolidation. Subsequently, using a second batch of rats, dose-response curves for both PF-999 and roflumilast were validated followed by combination treatments of suboptimal and optimal doses of both compounds. The vehicle condition was tested by means of a single injection for the dose-response curves and two vehicle injections were used as an ultimate control for the

combination treatments. Because rats were retested with different compound doses using a randomized crossover design, test sessions were scheduled to allow at least a two-day wash-out period. The order of the treatments was balanced to prevent the data from being distorted by potential object- and side-preferences of the animals.

### **Rat Pharmacokinetics Determination**

Pharmacokinetic properties of PF-999, roflumilast, roflumilast N-oxide, and their combination in male SD rats were determined using standardized procedures as described previously with the exception of vehicle and doses tested (Santora et al., 2018). Briefly, pharmacokinetics properties in male SD rats (300–350 g) were determined following oral (PO) administration (N = 3, 0.1 mg/kg). Rats were catheterized in femoral vein. PF-999 and roflumilast were formulated in 0.5% Methyl 2-hydroxyethyl cellulose (Tylose® MH300) and 2% Tween80. Rats were not fasted during this study. Blood was sampled at 0 (pre-dose), 0.25, 0.5, 1, 2, 4, and 8 h following PO dosing. Plasma was isolated by centrifugation, and all samples were frozen at –80 °C. Calibration standards were prepared by the addition of known concentrations of test article to blank rat plasma to provide a calibration range of 0.5–2000 ng/mL. Then 50 µL plasma samples or calibration standard was added to 250 µL of internal standard solution in acetonitrile. Samples were vortex mixed and centrifuged at 12000 rpm for 5 min at 4 °C. Supernatant (100 µL) was transferred to labeled autosampler vials containing 300 µL of mobile phase (water/acetonitrile/formic acid, 90/10/0.2%), vortex mixed, and analyzed by LC-MS/MS. A bioanalytical method was developed for the quantification of test article in rat plasma. Method development and sample analysis was conducted using a Waters Quattro Premier LC-MS/MS system equipped with Waters Acquity UPLC system. Then 5 µL of the samples were analyzed using a Waters Acquity UPLC system equipped with a C 18 reversed-phase column (Phenomenex Kinetex C18, 1.7 µm, 2.1 mm × 50.0 mm). Mobile phase consisted of 0.1% formic acid in water and of 0.1%

formic acid in acetonitrile with a flow rate of 0.7 mL/min. Eluent was directed to a Waters Quattro Premier mass spectrometer equipped with a turbo electrospray interface. Multiple reaction monitoring (MRM) transition in positive ion mode was used.

For CNS penetration studies male SD rats (300–350 g) were dosed PO (N = 3, 10 mg/kg). PF-999 was formulated in NMP:PEG400:water (10:30:60), and roflumilast was formulated in PEG400:water (20:80). Animals were anesthetized, and approximately 0.3 mL of blood from each rat was collected via cardiac puncture into tubes containing lithium heparin as the anticoagulant at 1 h post dose. Plasma was isolated by centrifugation. Animals were then decapitated and brains were removed. All samples were stored frozen at approximately  $-80^{\circ}\text{C}$  until analysis. Plasma analysis was performed as described above. One hemisphere of each brain sample was weighed. One to five dilutions (w/v) were prepared by addition of 1:1 mixture of water/2-propanol (4-fold of the brain weight) to each brain sample. Brains were homogenized by Fast Prep Calibration standards (ranging from 0.500 to 2000 ng/mL), quality control samples, and test samples containing the internal standard (IS) were separated from rat brain preparations via protein precipitation by addition of 100  $\mu\text{L}$  of 75:25 acetonitrile/water solvent containing analyte calibrants and 300  $\mu\text{L}$  of acetonitrile/IS solution mix (40 ng/mL in acetonitrile) to 100  $\mu\text{L}$  brain homogenate. Following vortex mixing and centrifugation, 20  $\mu\text{L}$  aliquots of the supernatants were diluted with 580  $\mu\text{L}$  of 20:80 acetonitrile/water containing 0.2% formic acid and mixed for the 10 mg/kg study. Following vortex mixing and centrifugation, 100  $\mu\text{L}$  aliquots of the supernatants were diluted with 300  $\mu\text{L}$  of 10:90 acetonitrile/water containing 0.2% formic acid and mixed for the 1.0 mg/kg study. Then 5  $\mu\text{L}$  of each sample was applied to a Kinetex 1.7  $\mu\text{m}$  C18, 100  $\text{\AA}$ , 50 mm  $\times$  2.1 mm column (Phenomenex, Torrance, CA) and eluted with a mobile phase gradient (initial 10% B hold for 0.1 min, then 10% B to 90% B in 1.0 min) consisting of solution A (0.1% formic acid in water) and solution B (0.1% formic acid in acetonitrile). The

column temperature was maintained at 30 °C. The column eluent was subjected to positive-mode electrospray ionization (ES+), and the analytes were detected with a QTrap 5500 quadrupole/ion trap mass spectrometer (AB Sciex, Framingham, MA). Plasma binding and brain tissue binding was determined as described previously (Santora et al., 2018).

### **Statistical analysis**

The ratio of p-GluR1 and GluR1 fluorescence intensity was calculated for striatal and cortical slices (n=3/condition). One-way ANOVA was performed to test for differences among conditions, followed by Bonferroni post-hoc t-tests. Quantification of p-GluR1/GluR1 was performed similarly in the experiment using fixed concentrations of either PF-999 or roflumilast combined with different doses of the other compound. After one-way ANOVA, Dunnett's post-hoc tests were performed comparing combined treatment conditions to the condition that was treated with only the fixed concentration of either PF-999 or roflumilast. In all analyses, an  $\alpha$  level of 0.05 was considered statistically significant.

Fluorescence induced by CRE-mediated transcription was quantified using a Cell InSight cell-content imager (Thermo Fisher Scientific) which automatically determined nuclear CRE-mCherry and Synapsin1-GFP levels for individual neurons. The ratio of mCherry to GFP was calculated for each individual neuron in 9 fields per well over triplicate wells used for each experiment. We performed 3 independent experiments and the normalized fluorescence values were then averaged (n=3/condition). One-way ANOVA was performed to test for differences in forskolin EC<sub>50</sub> values among conditions, followed by Dunnett's post-hoc t-tests.

For the object location task, the basic measures were the times spent by rats exploring an object during T1 and T2. The time spent in exploring the two identical samples will be represented by 'a1' and 'a2'. The time spent in T2 in exploring the sample and moved object will be represented by 'a3' and 'b', respectively. The

following variables were calculated:  $e1 = a1 + a2$ ,  $e2 = a3 + b$ , and  $d2 = (b - a3) / e2$ .  $e1$  and  $e2$  are measures of the total exploration time of both objects during T1 and T2 respectively. Animals that exhibited  $e1$  and  $e2$  values of less than 5 or 8 seconds were excluded from the analysis, since no reliable conclusions can be drawn from short exploration times (Akkerman et al., 2012b). The  $d2$  index is a relative measure of discrimination corrected for exploratory activity in the test-trial ( $e2$ ). Thus, even if a treatment would affect exploratory behavior, the  $d2$  index will be comparable between conditions. One-sample t-statistics were performed in order to assess per treatment condition whether  $d2$  differed from zero. However, comparison of the mean  $d2$  value with the value zero may not be the most suitable way for analyzing memory performance (increased chance of making a type I error). Results were therefore also assessed using one-way ANOVA. In case of a significant difference between treatment conditions, pairwise post-hoc comparisons were performed using Bonferroni t-tests.

## RESULTS

### Synergistic actions of PDE2 and PDE4 inhibition on striatal and cortical GluR1 phosphorylation

Phosphorylation of the AMPA receptor GluR1 subunit by PKA or PKG can promote synaptic plasticity by trafficking of the receptor to the membrane and increasing receptor conductance. Here we tested whether PDE2 and PDE4 inhibition affects GluR1 phosphorylation at Ser845 in rat striatal and cortical slices and whether combined treatment has additive effects. Slices were treated with PF-999, roflumilast, or both (1  $\mu$ M), and the ratio of phosphorylated GluR1 (p-GluR1 Ser845) and total GluR1 was measured.

**Figure 1. Effects of PDE2 and PDE4 inhibition on GluR1 phosphorylation.** A-B) The ratio of phosphorylation GluR1 (p-GluR1) and total GluR1 was measured in striatal and cortical rat brain slices treated with PF-999, roflumilast or both (1  $\mu$ M; n=3/condition). One-way ANOVA followed by Bonferroni post-hoc t-tests revealed that combined treatment significantly increased p-GluR1 compared to vehicle or individual treatment with PF-999 or roflumilast in both striatal and cortical slices (\*:P<0.05, \*\*\*:P<0.0001). In cortical slices, treatment with PF-999 alone increased p-GluR1 compared to the vehicle and roflumilast condition (P<0.001 and P<0.01, respectively. Not indicated in graph). C-D) Concentration-dependent effects of combined treatment were tested in cortical slices by using a fixed concentration of either PF-999 (300 nM, panel C) or roflumilast (30 nM, panel D) combined with increasing concentration of the other compound. One-way ANOVA followed by Dunnett's post-hoc t-tests revealed that administration of 12-409 nM roflumilast combined with 300 nM PF-999 significantly increases p-GluR1/GluR1 compared to treatment with PF-999 in absence of roflumilast (#:P<0.05, ###: P<0.001). Vice versa, when using a fixed roflumilast concentration combined with increasing concentrations of PF-999, one-way ANOVA and Dunnett's post-hoc t-tests shows that PF-999 can potentiate the effect of roflumilast in the 220-2200 nM concentration range (#:P<0.05, ###: P<0.001).

In striatum, one-way ANOVA revealed significant differences in p-GluR1/GluR1 ratio between conditions ( $F(3,8) = 10.13$ ,  $P < 0.01$ ; Fig 1A). Bonferroni post-hoc t-tests indicate increased p-GluR1/GluR1 ratio in the PF-999 and roflumilast condition compared to vehicle ( $P < 0.0001$ ) and PF-999 or roflumilast alone ( $P < 0.05$ ). Similarly, in cortex one-way ANOVA revealed significant differences in p-GluR1/GluR1 ratio between conditions ( $F(3,8) = 140.2$ ,  $P < 0.0001$ ; Fig 1B). Bonferroni post-hoc t-tests indicate a significant higher p-GluR1/GluR1 ratio in the PF-999 condition compared to vehicle ( $P < 0.001$ , not shown in Fig 1B), and a non-significant trend with roflumilast alone ( $P = 0.09$ , not shown in Fig 1B). Additionally, combined treatment with PF-999 and roflumilast was found to significantly increase p-GluR1/GluR1 ratio compared to vehicle (\*\*\*:P < 0.0001) and PF-999 or roflumilast alone (\*\*\*:P < 0.0001 for both). These findings indicate that PF-999 can increase cortical p-GluR1 and that combined administration of PF-999 and roflumilast has additive effects on p-GluR1/GluR1 ratio in both striatal and cortical slices.

To test whether these additive effects are concentration-dependent, we established concentration-response curves by pairing increasing concentrations of either PF-999 or roflumilast with a low dose of the other compound that only causes minimal increases in pGluR1 by itself (Fig 1C and 1D). When combining a fixed concentration of PF-999 (300 nM) with increasing doses of roflumilast (0-409 nM), a dose-dependent effect on cortical p-GluR1/GluR1 ratio is observed (Fig 1C). One-way ANOVA of PF-999 conditions in combination with roflumilast (0-409 nM, black bars) revealed significant differences in p-GluR1/GluR1 ratio between conditions ( $F(5,42) = 11.08, P < 0.0001$ ). Compared to treatment with PF-999 alone, significant increases in p-GluR1/GluR1 ratio were found when roflumilast (12-409 nM) was added (12-123 nM, ###:  $P < 0.001$ ; 409 nM, #:  $P < 0.05$ ; Dunnett's post-hoc t-tests). No significant effect was found upon combined treatment of 300 nM PF-999 with 4 nM roflumilast. Treatment with roflumilast (409 nM) or PF-999 (300 nM, Fig 1C) alone was ineffective (Fig 1C), as was treatment with lower doses of roflumilast (4-123 nM, data not shown). These findings indicate that PDE4 inhibition in addition to PDE2 inhibition significantly increases the amount of phosphorylated GluR1.

Vice versa, when using a fixed concentration of roflumilast (30 nM) in combination with increasing PF-999 concentrations (0-2200 nM), concentration-dependent effects on p-GluR1/GluR1 were observed as well (Fig 1D). One-way ANOVA of roflumilast conditions in combination with PF-999 (0-2200 nM, black bars) revealed significant differences in p-GluR1/GluR1 ratio between conditions ( $F(5,12) = 11.08, P < 0.0001$ ). Compared to treatment with roflumilast alone, significant increases in p-GluR1/GluR1 ratio were found when PF-999 (220-2200 nM) was added (220 nM, #:  $P < 0.05$ ; 733-2200, ###:  $P < 0.001$ ; Dunnett's post-hoc t-tests). No significant increase was found upon combined treatment of 30 nM roflumilast with 22-73 nM PF-999. Thus, synergy was seen with combined administration of PF-999 and roflumilast at a variety of drug concentrations, with PDE2 to PDE4  $IC_{50}$  ratios ranging from 1-30x.

### **PDE2 and PDE4 inhibition synergistically increases CRE-mediated gene expression**

As long-term memory critically depends on gene transcription mediated by CREB, we investigated whether inhibition of PDE2 and PDE4 synergistically induces CRE-mediated expression in primary cortical cultures. After infection with ratiometric fluorescent reporter, the effect of PDE2 and PDE4 inhibition on CRE-mediated gene expression was studied by measuring CRE-mCherry fluorescence intensity upon exposure to a concentration range of forskolin (0-10  $\mu$ M) to stimulate cAMP production and treatment with PF-999, roflumilast or their combination (Fig 2). One-way ANOVA revealed significant differences between  $EC_{50}$  values for forskolin ( $F(3,8) = 7.22$ ,  $P < 0.05$ ). Dunnett's post-hoc t-tests indicated a significantly lower  $EC_{50}$  of forskolin for the combined PF-999 and roflumilast condition ( $EC_{50} = 0.70 \mu$ M) compared to vehicle ( $EC_{50} = 1.62 \mu$ M;  $P < 0.01$ , not indicated in Fig 2A). Roflumilast treatment, but not PF-999, augmented CRE-reporter expression in the presence of forskolin, while combination of both inhibitors greatly increased the overall signal (Fig 2B/C). These findings indicate that combined treatment with PF-999 and roflumilast facilitates CRE-mediated gene expression upon stimulation with lower levels of forskolin.

**Figure 2. Effect of PDE2 and PDE4 inhibition on forskolin-induced CRE-mediated gene expression.** The effect of PDE2 and PDE4 inhibition on CRE-mediated gene expression was investigated in cortical neurons infected with a ratiometric fluorescent reporter of CRE-mediated transcription. Neurons were stimulated with forskolin (0-10  $\mu\text{M}$ ) and additionally treated with PF-999, roflumilast or both compounds (1  $\mu\text{M}$ ) and the nuclear mCherry:GFP ratio indicated the amount of CRE-mediated gene expression. A) Forskolin dose response (left panel), and a representative image is shown of Map-2(+) cortical neurons (white) expressing both GFP and mCherry fluorescence as well as a schematic depiction of the fluorescent reporter (right panel). B/C) Significantly higher fluorescence intensities were measured for combined treatment with PF-999 and Roflumilast compared to vehicle and PF-999 or roflumilast alone in the presence of Forskolin (ANOVA at 42 nM Forskolin:  $F(3,8) = 98.40$ ,  $P < 0.0001$ , Bonferroni post-hoc test  $P < 0.001$  for PF-999 + Roflumilast vs. all other conditions; ANOVA without Forskolin:  $F(3,8) = 3.56$ ,  $P = 0.07$ ). Without Forskolin, PDE4 inhibition had small but non-significant effect on CRE-reporter expression. No effect was seen for PDE2 inhibition alone.

### **Combined administration of roflumilast and PF-999 improves spatial object memory in rats**

The previous experiments indicated that combined PDE2 and PDE4 inhibition modulates neuronal signaling intricately linked with synaptic plasticity and long-term memory. Hence, we sought to investigate whether PDE2 and PDE4 inhibition can facilitate memory consolidation *in vivo*. By means of oral administration of different doses PF-999 or roflumilast to rats 3 h after the training trial of an object location task, effective doses of each of the compounds were determined. The delay interval between the first and second trial was 24 h. Memory performance, as indicated by the discrimination index ( $d_2$ ), was significantly different from chance (zero) in animals that received 0.3 mg/kg PF-999 or 0.3 mg/kg roflumilast, as indicated by one-sample t-tests (Fig 3, left and middle panel). No significant effect on memory was detected with lower doses of PF-999 or roflumilast. For PF-999, one-way ANOVA revealed significant differences in  $d_2$  between treatment conditions ( $d_2$ :  $F(3, 68) = 3.94$ ,  $P < 0.05$ ). Post-hoc Bonferroni t-tests revealed that rats treated with 0.3 mg/kg PF-999 showed significantly better object discrimination when compared to vehicle ( $P < 0.05$ ) and 0.1 mg/kg PF-999 ( $P < 0.05$ ). For roflumilast, one-way ANOVA also revealed significant differences in  $d_2$  between treatment conditions ( $d_2$ :  $F(3, 44) = 6.97$ ,  $P < 0.001$ ). Rats receiving 0.3 mg/kg roflumilast showed significantly better object discrimination when compared to vehicle ( $P < 0.001$ ) and 0.1 mg/kg roflumilast ( $P < 0.01$ ; Bonferroni post-hoc t-test). This indicates that post-trial administration of doses 0.3 mg/kg PF-999 or roflumilast 3 hrs after learning enhanced memory measured 24 hours later in our NOL paradigm.

After determining effective doses of PF-999 and roflumilast we asked if combined administration of highest ineffective doses (i.e. 0.1 mg/kg) of both compounds can exert synergistic effects on memory consolidation. We treated rats with vehicle, roflumilast or PF-999 alone, or a combination of both. When memory recall was tested 24-hrs after training, the discrimination index ( $d_2$ ) significantly differed from chance in animals that received the combined administration of 0.1

mg/kg PF-999 and roflumilast, but not in rats treated with vehicle or either compound alone (Fig 3, right panel). One-way ANOVA revealed significant differences between treatment conditions (d2:  $F(3, 77) = 5.29, P < 0.01$ ). Post-hoc Bonferroni t-tests revealed that rats treated with the combination of PF-999 and roflumilast (0.1 mg/kg for both compound) showed significantly higher object discrimination compared to vehicle ( $P < 0.001$ ) and 0.1 mg/kg roflumilast condition ( $P < 0.05$ ).

**Figure 3. Effects of increasing doses PF-999 and roflumilast and the combination of highest ineffective doses on spatial memory consolidation.** Compared to the vehicle condition, both PF-999 (left panel) and roflumilast (middle panel) injected p.o. 3 h after T1, improved memory performance at a dose of 0.3 mg/kg. A difference from chance is depicted with asterisks (one sample t-tests, \*\*\*:  $P < 0.001$ ). One-way ANOVA revealed significant differences for the discrimination index d2 between treatment conditions for PF-999 (d2:  $F(3, 68) = 3.94, P < 0.05$ ) as well as for roflumilast (d2:  $F(3, 44) = 6.97, P < 0.001$ ). Combination of the highest ineffective dose of 0.1 mg/kg (right panel) improved memory compared to vehicle, and yielded memory performance significantly different from chance. Differences between conditions are indicated with dollar signs (Bonferroni post-hoc t-test, \$:  $P < 0.05$ , \$\$:  $P < 0.01$ , \$\$\$:  $P < 0.001$ ).

### Combined administration of effective and ineffective doses of PF-999 and roflumilast

In a second study, we aimed to confirm our finding of synergy and determine dose-responses for the drug combination using a second batch of animals. Here again, memory performance was significantly higher than zero in animals that received 0.3 mg/kg PF-999 or 0.3 mg/kg roflumilast, as indicated by one-sample t-

tests, but not at 0.1 mg/kg of either drug (Fig 4, left and middle panel). Then, combined administration of subeffective and effective doses PF-999 and roflumilast was tested at doses 0.03, 0.1, and 0.3 mg/kg. We found that animals that received 0.1 or 0.3 mg/kg of both PF-999 and roflumilast showed significant memory recall 24 hours after testing (Fig 4, right panel; one-sample t-test vs. chance). One-way ANOVA revealed significant differences between treatment conditions (d2:  $F(3, 77) = 5.23$ ;  $P < 0.01$ ). Bonferroni post-hoc analysis showed that the combination of PF-999 and roflumilast at doses of 0.1 or 0.3 mg/kg administered 3 h after T1 significantly improved object discrimination performance when compared to the vehicle condition ( $P < 0.05$ ). Thus, treatment with PF-999 and roflumilast at doses of 0.1 or 0.3 mg/kg prevents time-dependent forgetting of rats. As 0.1 mg/kg was a subefficacious dose for both compounds when administered separately, these results demonstrate synergistic effects of combined PDE2 and PDE4 inhibition on memory consolidation.

**Figure 4. Effects of increasing doses PF-999 and roflumilast and their combined administration on spatial memory consolidation.** Compared to the vehicle condition and zero, single administration of either PF-999 (left) or roflumilast (middle) at a dose of 0.3 mg/kg improved memory performance. One-way ANOVA revealed significant differences for the discrimination index d2 between treatment conditions in the PF-999 dose-response curve (d2:  $F(2, 36) = 18.57$ ;  $P < 0.001$ ) and roflumilast dose-response curve (d2:  $F(2, 33) = 5.75$ ;  $P < 0.01$ ). The combination of PF-999 and roflumilast (right) at doses of 0.1 and 0.3 mg/kg injected 3 h after T1, improved memory performance compared to the vehicle condition. A difference from zero is depicted with asterisks (one sample t-tests, \*\*:  $P < 0.01$ , \*\*\*:  $P < 0.001$ ). One-way ANOVA revealed significant differences for the discrimination index d2 between treatment conditions (d2:  $F(3, 77) = 5.23$ ,  $P < 0.01$ ). Differences between conditions are indicated with dollar signs (Bonferroni post-hoc t-tests, \$:  $P < 0.05$ ).

### **Pharmacokinetics of individual and combined administration of PF-999 and roflumilast**

Since combined treatments may influence the pharmacokinetics of individual compounds, a pharmacokinetic profile was established for PF-999 and roflumilast upon individual and combined administration in rats. Plasma concentrations were determined at doses of 0.1 mg/kg p.o. (N=3; Table 1). These measurements indicated that both compounds yielded similar plasma  $C_{max}$ ,  $T_{max}$ , and  $AUC_{0-inf}$  when administered alone or in combination. We also evaluated exposures of N-oxide metabolite of roflumilast, which potently inhibited PDE4D3 ( $IC_{50} = 0.75nM$ ), and there was no difference. Thus, combined administration of our inhibitors did not change oral absorption or metabolism of roflumilast to the bio-active N-oxide. Estimated brain concentrations for PF-999 were 0.334 and 0.420 ng/ml when dosed individually or in combination with roflumilast, corresponding to 1.8-2.4 times the  $IC_{50}$  for PDE2 inhibition. For roflumilast, brain concentrations of 0.112 and 0.106 ng/ml were estimated upon individual or combined dosing with PF-999. With an  $IC_{50}$  of 0.234 nM roflumilast at PDE4D3, these estimated brain concentrations are 1.1-1.2 fold higher than the  $IC_{50}$ . Estimated brain exposure of the N-oxide was 1.9-fold higher than the  $IC_{50}$  to inhibit PDE4D3. Thus, the sub-efficacious 0.1 mg/kg dose yielded relative exposures of 1-2x  $IC_{50}$  to inhibit PDE2 or PDE4, respectively.

**Table 1** Pharmacokinetic properties of PF-999 and roflumilast when administered individually and combined.

## DISCUSSION

In the current study, we investigated whether combined inhibition of PDE2 and PDE4 can improve memory consolidation processes. First, the effect of PDE2 and PDE4 inhibition, using PF-999 and roflumilast respectively, on GluR1 phosphorylation was tested in striatal and cortical rat brain slices. Ser845 phosphorylated GluR1 subunits have been found to specifically localize to learning-associated synapses (Matsuo et al., 2008). In striatal slices, combined application of PF-999 and roflumilast significantly promoted GluR1 phosphorylation. In cortical slices, application of PF-999 alone was found to significantly increase GluR1 phosphorylation. This effect was augmented by combined treatment of PF-999 and roflumilast. Earlier studies indicated that separate inhibition of PDE2 or PDE4 can increase GluR1 trafficking to the membrane (Park et al., 2016; Song et al., 2016); a process dependent on serine 845 phosphorylation (Oh et al., 2006). Also, membrane insertion of calcium-permeable AMPA receptors involved in hippocampal LTP is reported to be dependent on PKA signaling (Park et al., 2016). As GluR1 can be phosphorylated by both PKA and PKG, combined PDE2 and PDE4 inhibition may significantly increase both PKA and PKG activity leading to higher p-GluR1/GluR1 ratios. Taken together, these findings suggest that PF-999 and roflumilast increase GluR1 phosphorylation through synergistic actions.

In addition, the effect of PDE2 and PDE4 inhibition on forskolin-stimulated CRE-mediated expression was tested in cortical neurons. CRE-mediated expression is activated by PKA- and PKG-signaling to CREB (Kandel, 2012), which in turn is stimulated by elevated cyclic nucleotide levels. We found that CRE-mediated expression is stimulated by significantly lower concentrations of forskolin when treated with PF-999 and roflumilast, but not when treated with either inhibitor alone. These seemingly synergistic actions of dual inhibition are comparable to those found for GluR1 phosphorylation as inhibition of one PDE family induces effects which are potentiated by additional inhibition of the other PDE family. The current findings are

consistent with previous studies showing that inhibition of PDE4 and PDE2 can increase CREB phosphorylation (Asanuma et al., 1996; Feng et al., 2019; Lueptow et al., 2016; Soares et al., 2017; Zhong et al., 2016). Another study found that PDE2 inhibition does not increase CREB phosphorylation but restores corticosterone-induced decreases in CREB binding protein (CBP) in mouse hippocampal neurons (Xu et al., 2013). CBP serves as a co-activator of CREB and may thus stimulate CREB-mediated transcription upon increased CREB phosphorylation induced by PDE4 inhibition.

To demonstrate synergistic effects *in vivo*, an object location task was used to test the effects of PF-999 and roflumilast on spatial memory performance in rats. Specifically, the effects of both compounds were investigated on late memory consolidation by means of oral administering 3 h after the learning trial. A dose of 0.3 mg/kg was found to be effective for both compounds when administered individually. Subsequently, sub-effective and effective doses were combined (0.1 and 0.3 mg/kg, respectively for both PF-999 and roflumilast) to investigate potential synergistic effects on memory consolidation. Delay-dependent forgetting could be fully prevented by treating animals with combinations of both sub-effective and effective doses. Thus, combining doses of PF-999 and roflumilast, which by themselves are ineffective, can improve spatial memory performance in rats suggesting cooperative actions on underlying molecular mechanisms. Additional pharmacokinetic profiling of PF-999 and roflumilast upon individual or combined administration indicated that combined administration does not influence exposure to either PF-999 or roflumilast. Determined  $IC_{50}$  concentrations were consistent with previously reported values for PF-999 (Helal et al., 2017) and roflumilast (Hatzelmann et al., 2010). Brain concentrations [free+bound] ranged from 1-2x the  $IC_{50}$  (i.e. 50% enzyme inhibition) after a dose of 0.1 mg/kg. However, because of high protein binding, we anticipate that free brain concentrations of roflumilast are well below  $IC_{50}$  at efficacious exposures. However, brain levels of the active roflumilast N-oxide

metabolite were higher, and the estimated free brain concentration of PF-999 was 0.7x IC<sub>50</sub>[PDE2] at the efficacious dose of 0.3 mg/kg, and 0.29x IC<sub>50</sub> [PDE2] at the 0.1 mg/kg sub-effective dose. Our findings are in accordance with studies in nonhuman primates and humans in which memory-enhancing doses led to low brain PDE4 occupancy levels (Takano et al., 2018; Van Duinen et al., 2018). Furthermore, while higher doses would occupy more PDE4 sites, these doses do not show memory enhancing effects in mice (Vanmierlo et al., 2016). Similarly, receptor occupancy as measured by PET is below the detectable level after PF-999 doses of 0.1-0.3 mg/kg (Gu et al., 2019). The latter finding is consistent with observations on PDE2 inhibitor TAK-915, a compound that reverses NMDA receptor antagonist induced memory impairment at brain occupancy levels of 46-63%, but enhances object recognition memory in intact rats at doses that are 30- to 100-fold lower (Mikami et al., 2017). Overall, these results indicate that PDE2 and PDE4 inhibitors can exert profound effects on behavior even at low brain concentrations. Our *in vitro* studies in cortical slices tested fixed drug concentrations of either 300 nM PF-999 or 30 nM roflumilast with varying concentrations of the PDE4 and PDE2 inhibitors, respectively. Inhibitor concentrations were set to induce a minimal pGluR1 signal that could be facilitated by adding the corresponding inhibitor for the other PDE. The lowest concentration of roflumilast required for elevating pGluR1 in cortical slices when PDE2 was inhibited by PF-999 was 12 nM (51x IC<sub>50</sub>), and the lowest dose of PF-999 required for elevating pGluR1 was between 73 nM and 220 nM (166–500x IC<sub>50</sub>). These drug concentrations are much higher than what was measured in brain post memory enhancing doses *in vivo*. Here again, a disconnect between biochemical surrogate measures of memory (pGluR1 in our study) and *in vivo* exposures in memory models has also been observed with TAK-915. The latter compound potently inhibits PDE2 (IC<sub>50</sub> = 0.61 nM) and enhances memory in intact young rats at oral doses of 0.1 mg/kg, but it requires doses of 10 mg/kg with corresponding brain concentrations of 331 ng/ml (723 nM) for enhancing hippocampal and cortical pGluR1 and cGMP *in vivo* (Mikami et al.,

2017; Nakashima et al., 2018). It is likely that neuromodulatory input and  $\text{Ca}^{2+}$ -signaling resulting from synaptic activity during memory encoding are not preserved in the slice system, and inadequately modelled when animals are exposed to drug in the absence of behavior *in vivo*. Our exploration focused on GluR1 Ser845 phosphorylation and CRE-mediated gene-expression as exemplary cyclic nucleotide regulated mechanisms linked to memory consolidation and synaptic plasticity in the hippocampus and neocortex. However, PDE2 and PDE4 may have additional effects on transmitter release (Fernandez-Fernandez et al., 2015), dopaminergic receptor signaling (Polito et al., 2013), and excitation/inhibition balance in dopaminergic systems (Liu et al., 2017) not explored here. Thus, simultaneous augmentation of multiple mechanism may underlie the increased sensitivity to PDE inhibition *in vivo*.

The phosphorylation of the AMPA receptor GluR1 subunit is required for synaptic plasticity and retention of spatial memory (Lee et al., 2003). The synergistic effects of PDE2 and PDE4 inhibition on GluR1 phosphorylation paired with increased CREB phosphorylation may therefore have contributed to the improved spatial memory performance. Interestingly, inhibition of PDE5 - rather than PDE4 - increased GluR1 trafficking to the membrane in mice (Argyrousi et al., 2020). Subeffective dose combination of rolipram (PDE4 inhibitor) and vardenafil (PDE5 inhibitor) at different time points can also improve memory performance in rats (Bollen et al., 2015). More recently, combined treatment for three weeks with subeffective doses of roflumilast (0.01 mg/kg) and vardenafil (0.1 mg/kg) was found to restore memory impairments in APP<sup>swe</sup> mice (Gulisano et al., 2018). These studies support our finding that inhibition of different PDE families may jointly exert memory enhancing effects. Through partial activation of multiple distinct mechanisms, which may act sequentially or concurrently, behavioral plasticity is effectively enhanced. We focused here on two key mechanism of memory formation, AMPA receptor phosphorylation and CRE-mediated gene expression. While combined inhibition greatly enhanced both, we cannot be entirely sure that effects on GluR1 phosphorylation was more

sensitive to PDE2 and CRE-mediated transcription more sensitive to PDE4 inhibition. These findings may imply that the PDEs regulate cyclic nucleotide levels in different intracellular compartments. PDE2 and PDE4 have been implicated in the regulation of both pre- and postsynaptic signaling (Fernandez-Fernandez et al., 2015; Liu et al., 2017; Polito et al., 2013). PDE2A protein is detected in pyramidal neurons and interneurons of rat neocortex, and it is highly concentrated in axons and nerve terminals of the mossy fiber pathway in hippocampus (Stephenson et al., 2009). Elevations in cGMP and cAMP levels upon NMDA receptor activation are regulated by respectively PDE2 and PDE4 (Suvarna and O'Donnell, 2002). As certain PDE2 and PDE4 transcript variants are known to associate with the membrane, they may be positioned within signaling complexes that regulate the phosphorylation of pre- and post-synaptic targets, including AMPA receptors (Bender and Beavo, 2006). The PDE2A3 isoform is localized to presynaptic membranes and may mediate the effect of PDE2A inhibitors on presynaptic plasticity (Fernandez-Fernandez et al., 2015; Russwurm et al., 2009). The PDE4D3 and PDE4D5 isoforms are localized to the perinuclear region and within the nucleus, respectively, which enables PDE4 to predominantly exert control on the cAMP-PKA-CREB signaling axis which eventually leads to CRE-mediated transcription (Boczek et al., 2019; Clister et al., 2019). PDE2 and PDE4 may thus be involved in distinct but partly overlapping or cross-talking signaling cascades which, upon combined inhibition, can produce synergistic effects on plasticity. Correspondingly, PDE2 and PDE4 inhibition can both inhibit endothelial cell proliferation, but exert these effects through different mechanisms (Favot et al., 2004).

An open question remains whether combined inhibition of PDE2 and PDE4 is efficacious and synergy is seen in models of memory impairment. An interesting finding in this context was reported by Gulisano et al., who found that combined PDE4 and PDE5 inhibition can improve memory in transgenic AD mice only with chronic dosing (Gulisano et al., 2018). In addition, much higher concentrations of

PDE2 inhibitors may be required to reverse memory impairment than tested here in normal adult rats (Gu et al., 2019; Mikami et al., 2017; Nakashima et al., 2018). Hence, the memory-enhancing effect of combined PDE2 and PDE4 inhibition in disease models remains to be investigated. Nevertheless, the fact that subeffective doses PF-999 and roflumilast can synergistically increase memory consolidation through modulation of plasticity processes may provide a new therapeutic strategy. CNS expression of PDE2 is largely conserved between rat, primates, and humans (Stephenson et al., 2009), whereas human expression of the many PDE4 isoforms may vary substantially when compared to preclinical species. Thus, combining two targets with well characterized effects on memory in preclinical models may de-risk clinical translation of PDE biology arising from complications associated with variation of gene expression between species. Furthermore, because efficacy is achieved at lower levels of PDE4 inhibition, target related side effects such as emesis may be minimized. More generally, dual inhibitors of phosphodiesterases may open significant new avenues for the development of plasticity enhancers with improved efficacy.

## **ACKNOWLEDGEMENTS**

We would like to thank Laurent Gomez for critical discussions, Finley Serneo and Yan Beaver for CRE-luci studies, and John Nikpur for help with DMPK studies.

# Chapter 7

## General Discussion

The inhibition of PDE4 and, in particular, PDE4D has previously been investigated as a therapeutic strategy to treat memory problems associated with Alzheimer's disease (AD) (Cheng et al., 2010; Feng et al., 2019; Sierksma et al., 2014; Wang et al., 2020a; Zhang et al., 2018). While PDE4(D) inhibitors can potentially increase neuroplasticity processes *in vitro* and *in vivo*, the progression of these molecules into the clinic has been hampered by severe adverse effects, including nausea, emesis and diarrhea. As such, more specific PDE4(D) inhibitory treatments might be of great added value, maximizing their therapeutic effects while minimizing or preventing side effects. Interestingly, PDE4 enzymes consist of several subtypes and isoforms which are expressed in tissue-specific and cell-type specific patterns (Miró et al., 2002a; Miró et al., 2002b; Paes et al., 2021; Pérez-Torres et al., 2000). Moreover, within distinct cell types, PDE4D isoforms can locate to specific intracellular compartments to control cAMP signaling with high spatial resolution. As such, targeting of specific PDE4D isoforms can provide the necessary treatment selectivity to prevent PDE4(D)-mediated side effects of non-specific PDE4(D) inhibitors, while conserving the therapeutic effects.

### **Picking the best isoform as therapeutic target in AD**

Since PDE4D isoforms potentially provide better targets, an understanding of the differently described isoforms had to be established. As also outlined in **Chapter 2** (Paes et al., 2021), the nomenclature of PDE4 isoforms is complicated due to the existence of both mRNA transcript variants and protein isoforms that are differentially annotated within and across online genome browsers. Moreover, naming of PDE4 isoforms may not be consistent across species (see Supplementary Table 1 in **Chapter 2**). Building on the understanding of isoform-specific sequences at the DNA, mRNA, and protein level, PDE4D isoform-specific expression was measured in post-mortem brain tissue of Alzheimer's disease (AD) patients and matched healthy controls. As described in **Chapter 3**, mRNA expression of specific

PDE4D isoforms (PDE4D1, -D3, -D5, and -D8) was found to be upregulated in AD brains and these expression changes were found to be associated with altered DNA methylation of isoform-specific promoter regions in the *PDE4D* gene (Paes et al., 2020a). Moreover, these changes in expression and DNA methylation correlated significantly with measures of AD pathology (amyloid- $\beta$  plaques, tau tangles, and Braak staging) and cognitive impairment (Mini-Mental State Examination score, MMSE). Similar findings were gathered in experiments described in **Chapter 4**, in which isoform-specific PDE4D expression increases were found in the hippocampus and frontal cortex of transgenic AD mice (Paes et al., 2023). Whilst intriguingly translational between men and mice, these correlations between AD phenotype and PDE4D expression do not automatically imply causality. In addition, the directionality of a possible causal relationship between PDE4D isoform expression and AD pathology cannot be inferred directly from this work. In platelets, increasing cAMP levels inhibits the production of amyloid- $\beta$  (Sepúlveda et al., 2019). A similar mechanism may exist in the AD brain in which elevated PDE4D isoform expression would decrease cyclic adenosine monophosphate (cAMP) levels leading to increased amyloid- $\beta$  production. Vice versa, cells exposed to inflammatory stimuli can upregulate PDE4 expression (Konrad et al., 2015), which may explain how AD pathology would increase PDE4D isoform expression. Indeed, in **Chapter 4**, it was described that hippocampal neurons acutely exposed to amyloid- $\beta$  show increased expression of certain PDE4D isoforms (Paes et al., 2023). If both causal directionalities exist in the (AD) brain, AD pathology could upregulate PDE4D expression, which increases amyloid- $\beta$  production, leading to a self-propagating cycle. Promisingly, a recent conference abstract suggests that pharmacological PDE4D inhibition can lead to reduced amyloid- $\beta$  synthesis and increased amyloid- $\beta$  degradation (Xu, 2022). The interesting finding that PDE4D isoform expression is altered in AD should be seen as a first step as certain limitations in the associated study setup described in **Chapters 3 and 4** have to be considered. Importantly, since homogenized human and mouse

brain tissues were used in **Chapters 3** and **4** respectively, information regarding cell-type specific expression or even intracellular localization of PDE4D isoforms could not be determined. The yielded findings using homogenized tissues thus demonstrate the overall changes in PDE4D expression across many cells of different lineage; future studies could determine changes in expression, function, and intracellular localization of PDE4D isoforms in specific cell types. Moreover, PDE4D expression was measured at the mRNA level and can therefore not be directly translated to changes in protein levels or activity. Due to a lack of suitable commercial and non-commercial antibodies and the co-migration of multiple PDE4D isoforms on SDS-PAGE, it is extremely challenging, work intensive and expensive to assess protein expression levels of all specific PDE4D isoforms. Moreover, intracellular PDE4D isoform activity can also be altered via mechanisms independent of expression (e.g. through post-translational modifications as summarized in **Chapter 2**). Nevertheless, the studies described in **Chapters 3** and **4** indicate that certain PDE4D isoforms seem to be affected more or seem to be more important than others in the context of AD.

### **PDE4D isoforms in the regulation of neuronal plasticity**

Concurrent with altered PDE4D isoform expression, aberrant cAMP-PKA-CREB signaling was observed in the hippocampus of transgenic AD mice (**Chapter 4**), which will negatively impact neuroplasticity processes like neurite outgrowth (Batty et al., 2017; Mingorance-Le Meur and O'Connor, 2009). To validate the modulating role of PDE4D in regulating neuroplasticity, the effect of the PDE4D-selective inhibitor GEBR32a on neurite outgrowth was assessed in neuronal cell lines. In both a neuroblastoma (N2a) and hippocampal (HT22) cell line, exposure to GEBR32a elicited a concentration-dependent increase in neurite length (**Chapter 4**). Although it is convincing that GEBR32a can inhibit PDE4D based on the observations in this thesis and prior reports (Brullo et al., 2016; Cavalloro et al., 2020; Prosdocimi

et al., 2018; Ricciarelli et al., 2017), its selectivity towards PDE4D may not apply to studies using mice and murine cell lines. The putative binding mode by which GEBR32a achieves its PDE4D-selectivity involves an interaction with a PDE4D-specific phenylalanine present in the UCR2 region of long PDE4 isoforms (Cavalloro et al., 2020; Prosdocimi et al., 2018); PDE4A, -4B, and -4C, have a tyrosine instead. However, this phenylalanine residue represents a polymorphism that is present in primates, but not in mice (Burgin et al., 2010; Johnson et al., 2010). Therefore, PDE4D-selective binding of GEBR32a through interactions with a phenylalanine in UCR2 can likely not be achieved in murine cells like N2a and HT22 cells. It thus remains to be validated whether GEBR32a acts as a PDE4D-selective inhibitor in mice and murine cells. However, using a CRISPR-mediated genetic knockdown approach, the role of individual PDE4D isoforms in the regulation of neurite growth could be assessed in these murine cells (**Chapter 4**). It was found that all long PDE4D isoforms that are expressed in HT22 cells are involved in neurite growth regulation (i.e. PDE4D3, -D5, -D7, and -D9)(Paes et al., 2023). Specifically, genetic knockdown of these isoforms promoted neurite outgrowth and could protect against the neurotoxic, neurite-shortening effects of amyloid- $\beta$ . Interestingly, knockdown of PDE4D3 or PDE4D9 could completely overcome the neurotoxic effects of amyloid- $\beta$  on neurite growth and even induced longer neurites in those cells when compared to cells not exposed to amyloid- $\beta$ . Thus, ablation of specific long PDE4D isoforms can promote plasticity in neurons *in vitro*. It remains to be determined whether inhibition or genetic ablation of these specific isoforms improves neuroplasticity *in vivo* as well. Since neuroplasticity is a result of the spatiotemporal interaction of different cell types (e.g., neurons, astrocytes, microglia, and oligodendrocytes), it remains to be determined if the net effect of PDE4D isoform inhibition in different cell types will yield a functional improvement in neuroplasticity depending on the role of these PDE4D isoforms in other cell types.

Moreover, while genetic knockdown experiments indicate a clear involvement of specific long PDE4D isoforms in neuronal plasticity, it is not clear if these isoforms regulate the same cellular process. Isoform-specific adaptor proteins result in a distribution of isoforms to distinct intracellular compartments (**Chapter 2**, (Boczek et al., 2019a; Boczek and Kapiloff, 2020; Clister et al., 2019; Paes et al., 2021)). Based on this distinct localization, different PDE4D isoforms likely influence cAMP signaling in different compartments, while all long isoforms regulate neurite growth. Considering that different long PDE4D isoforms may regulate neurite growth in different compartments or signaling domains, it remains to be investigated whether simultaneous knockdown of more than one expressed long isoforms has an additive effect on promoting neurite growth. As mentioned for ablating a single isoform, the effect of inhibiting multiple isoforms on general neuroplasticity remains to be validated taking into account the different roles PDE4D isoforms play in different cell types.

Furthermore, the genetic knockdown experiments presented in this thesis have looked into relatively acute effects on neuroplasticity. In general, changes in intracellular signaling are followed by compensatory mechanisms to 'reset' the system. This principle also applies to PDE4-mediated signaling. The cAMP-PKA-CREB signaling axis, which would be stimulated upon PDE4(D) inhibition, regulates the transcription of several PDE4 isoforms (Le Jeune et al., 2002; Seybold et al., 1998; Swinnen et al., 1989). Inhibition of PDE4(D) can consequently induce cAMP-mediated compensatory mechanisms that would counteract the effects of the initial PDE4(D) activity inhibition. Therefore, in addition to the acute PDE4D isoform knockout experiments reported here, the chronic effects of PDE4D isoform knockout await to be determined. Of note in this respect, as PDE4 inhibition is known to have anti-inflammatory effects in different organs (Li et al., 2018), chronic PDE4(D) inhibition may also dampen neuro-inflammation in the AD brain which may actually contribute to overall therapeutic, memory-enhancing or memory-restoring effects.

## Considering isoform-specific PDE4 activity dynamics

In addition to transcription-based feedback, cAMP signaling is also dynamically regulated by a feedback mechanism at the protein level. More precisely, upon increasing cAMP levels, the downstream kinase protein kinase A (PKA) is activated which subsequently can phosphorylate and thereby enhance the enzymatic activity of long PDE4 isoforms specifically. By means of increased cAMP hydrolysis by these activated long PDE4 isoforms, elevated cAMP levels can be restored to baseline concentrations. Enzymatic activity modulation through, for example, phosphorylation by PKA, enables the dynamic control of cAMP levels by PDE4. As outlined in **Chapter 2**, several post-translational modifications like phosphorylation by PKA or interactions with other proteins can influence the enzymatic activity of specific PDE4(D) isoforms. As PDE4 activity regulation is a dynamic process as a result of positive and negative feedback loops, experimental investigation of the influence of isoform types on cAMP signaling using molecular biology techniques can be difficult. Therefore, a computational model was established to investigate the involvement of (activity modulation of) the different PDE4 isoform types in controlling cAMP levels (**Chapter 5**) (Paes et al., 2022). Taking into account the different proportions by which long, short, and supershort isoforms may be present, the simulations of the computational model indicated that long PDE4 isoforms exert the most profound control on cAMP signaling. The prominent effect of long isoforms is likely a result of the fact that their enzymatic activity is considerably increased upon phosphorylation by PKA. Consequently, inhibition of long isoforms specifically will yield the most substantial increase in cAMP levels. Thus, long PDE4(D) isoforms may be the most interesting pharmacological targets from a therapeutic perspective.

While a computational model can provide great insights into dynamic processes that are hard to disentangle in a biological system, a model is inherently limited to the parameters that are being considered. Several factors that are known to shape cAMP signaling and its control by PDE4 enzymes were not included in the

model described in this thesis. Firstly, PDE4 subtypes, PDE4 isoform types, and specific PDE4 isoforms within these type categories localize to specific intracellular compartments rather than exhibiting a homogeneous distribution throughout the cell (Anton et al., 2022; Blackman et al., 2011). Secondly, while the effects of phosphorylation by PKA and ERK on PDE4 activity are most extensively studied and included in the model, the effects other modulators of (isoform-specific) PDE4 enzymatic activity as listed in **Chapter 2** were not simulated. Lastly, current simulations have only considered cAMP signaling during a relatively short timescale (i.e. several minutes). Other feedback mechanisms that occur at a larger timescale like the aforementioned transcription-based feedback of upregulation PDE4 isoforms are therefore not considered yet. Thus, as computational models become better in simulating the spatiotemporal control of cAMP signaling by PDE4 subtypes and isoforms based on increasing knowledge of the localization, activity and cell-type specific expression of these enzymes, these *in silico* approaches can provide a useful way to define new or better-specified therapeutic targets.

### **Long PDE4D isoforms as suitable therapeutic targets**

Several lines of evidence presented in this thesis indicate that specific targeting of long PDE4D isoforms provides an effective therapeutic strategy to promote neuroplasticity in the context of AD. A pivotal role for long isoforms in regulation neuroplasticity is supported by prior studies. It has been shown that inhibition of high-affinity rolipram binding sites (HARBS), which are predominantly provided by long isoforms, enhances neurite outgrowth and spatial memory (Boomkamp et al., 2014; Egawa et al., 1997). In addition, pharmacological and shRNA-based inhibition of long PDE4D isoforms has been demonstrated to improve memory function (Li et al., 2011; Ricciarelli et al., 2017; Zhang et al., 2018). Based on abovementioned mRNA expression analyses, the long isoforms PDE4D3 and PDE4D5 were found to be upregulated in hippocampal cells exposed to amyloid- $\beta$ , transgenic

mouse brains showing amyloid- $\beta$  pathology as well as in post-mortem human brain tissue of AD patients. Moreover, in these human brain samples, epigenetic signatures in the PDE4D3 and PDE4D5 promoters were found to be altered, which supports the observation of altered transcription. Moreover, through the use of isoform-specific CRISPR-Cas9 knockdown experiments, specific long PDE4D isoforms were found to regulate neurite length in mouse hippocampal neurons. Genetic knockdown of only those long PDE4D isoforms that were expressed by these cells led to a significant increase in neuronal plasticity (i.e. PDE4D3, -D5, -D7, and -D9). Provided the pivotal role of long PDE4 isoforms in regulating cAMP signaling, as validated using a computational model, inhibiting these forms will likely exert the most profound therapeutic effect. The question remains which of these long isoforms poses the ideal therapeutic target. An important aspect is that the exact involvement of these long PDE4D isoforms in PDE4-associated side effects remains to be determined. However, based on PDE4D isoform expression analysis presented in **Chapter 4**, it is clear that not all long PDE4D isoforms that regulate neuronal plasticity are expressed in the mouse stomach and therefore likely do not mediate peripherally regulated gastrointestinal side effects upon systemic PDE4(D) inhibition. Specifically, PDE4D7 and PDE4D9 are not highly expressed in the mouse stomach, while their genetic ablation does improve neuronal plasticity.

Looking into the robustness of findings, for several reasons, PDE4D3 may be the isoform to investigate in detail first. Firstly, PDE4D3 consistently showed increased expression within the human temporal lobe and mouse hippocampus and frontal cortex tissue displaying amyloid- $\beta$  pathology and mouse hippocampal neurons exposed to amyloid- $\beta$ . In fact, PDE4D3 expression correlated most strongly with levels of AD pathology and cognitive decline in the human material. Secondly, genetic PDE4D3 knockdown had the most profound effect on stimulating neurite outgrowth in mouse hippocampal cells and this knockdown could fully counter the neurite-shortening effect of amyloid- $\beta$  exposure. Thirdly, in different experimental

setups, Boczek et al. found that disrupting PDE4D3 from its perinuclear compartment resulted in enhanced neuronal survival and increased neurite outgrowth (Boczek et al., 2019b). Thus, PDE4D3-specific targeting may be an efficacious approach to stimulate neuroplasticity. However, as mentioned, side effects may still arise and, in particular for PDE4D3, cardiac side effects could occur considering the role of PDE4D3 in regulating ryanodine receptor functioning in the heart (Lehnart et al., 2005). Next to PDE4D3, PDE4D7 may be of interest as its role in gastro-intestinal side effects may be limited considering relatively low expression in the mouse stomach (**Chapter 4**) and in neurons of the human area postrema, which is involved in the central regulation of emesis (Vanmierlo, 2019). Moreover, the increase in enzyme activity upon phosphorylation by PKA is higher for PDE4D7 than any other long PDE4D isoform (Richter et al., 2005). This may imply that the relatively largest cAMP increase can be induced by inhibiting PDE4D7, considering equal expression of long isoforms.

### **Inhibitors selective for long PDE4D isoforms**

Irrespective whether inhibition of PDE4D3, PDE4D7, other long isoforms, or all long PDE4D isoforms contributes to the side effects observed upon non-specific PDE4 inhibition, targeting of long PDE4D isoforms may enhance therapeutic efficacy. The target specification towards specific isoforms has important implications for drug development. In order to develop PDE4 inhibitors that are selective towards the PDE4D subtype and long isoforms specifically, the sequence differences among subtypes and isoforms categories can be exploited (Blokland et al., 2019; Burgin et al., 2010; Paes et al., 2021). Because of their sequence, long PDE4D isoforms can dimerize which results in the capping of the regulatory UCR2 domain of one monomer across the catalytic domain of the other monomer (Cedervall et al., 2015; Houslay and Adams, 2010). Because of this configuration, specific amino acid residues of UCR2 extend into the catalytic domain with which inhibitor molecules can

interact to achieve specificity towards long isoforms. In fact, this trans-capping can be modulated when long isoforms are phosphorylated by PKA, which results in conformational changes that actually can increase the affinity of UCR2-engaging inhibitors (**Chapter 2, Table 4**). With long forms exerting most profound control on cAMP levels, UCR2-engaging long form inhibitors will create a positive feedback loop regarding their binding as the inhibition causes PKA activation, which in turn changes the enzyme conformation to promote inhibitor binding. However, it has also been described that as a result of dimerization, which is specific to long isoforms, UCR2-engaging inhibitors cannot achieve complete inhibition, as binding of the inhibitor to one monomer changes the enzyme's conformation which prevents proper inhibition of the other monomer (Burgin et al., 2010; Cedervall et al., 2015). As such, according to their binding mode, these types of inhibitor can be regarded as UCR2-engaging, long form-specific, PKA-activated specific, partial inhibitors.

While exploitation of these long form-specific structural features allows the development of long form-specific inhibitors, PDE4D selectivity is not yet achieved in this manner. However, as mentioned earlier, primates express a phenylalanine in the transcapping UCR2 region of PDE4D as opposed to a tyrosine for PDE4A, -4B, and -4C. Non-primate mammals express a tyrosine for all four PDE4 subtypes. Hence, inhibitors that specifically engage with this PDE4D-specific phenylalanine can achieve PDE4D selectivity (for primate PDE4 enzymes). This concept is described in detail by Burgin et al. and has led to the development of a PDE4D-selective inhibitor preferentially binding long isoforms. This molecule, called D159797, BPN14770 or Zanolmilast has been tested for its neuroplasticity-enhancing and memory-improving effects in *in vitro* and (pre)clinical *in vivo* studies (Berry-Kravis et al., 2021; Cui et al., 2019; Sutcliffe et al., 2014; Wang et al., 2020b; Zhang et al., 2018)[NCT03817684]. Although PDE4D inhibition has been associated with severe side effects through actions in brainstem areas like the area postrema that regulate emesis, this PDE4D-selective inhibitor did not show any adverse effects in behavioral

correlate measures of emetic behavior in humanized PDE4D mice at doses 300-fold higher than the therapeutic dose (Zhang et al., 2018). These humanized PDE4D mice express the human PDE4D sequence with a phenylalanine instead of tyrosine in the UCR2 region, which allows the engagement of PDE4D-specific inhibitors to exploit phenylalanine-dependent binding. In primates, emetic side effects were observed at orally administered doses of 1.5 mg/kg (Sutcliffe et al., 2014), which can be extrapolated to an emetic dose of 0.32 mg/kg for a human adult weighing 60 kg (Reagan-Shaw et al., 2008). Accordingly, administering 19.2 mg in humans is expected to be emetic, but a Phase I clinical study using BPN14770/zatolmilast showed no adverse effects upon administration of doses up to 40 mg, though at 100 mg vomiting was observed ([NCT02840279], <https://www.alzforum.org/news/conference-coverage/running-trial-results-ctad-conference>). The use of BPN14770 as pharmacological intervention against AD-associated memory deficits was further investigated in a Phase II clinical trial [NCT03817684]. While experimental outcomes have not been disclosed at the time of writing (August 2022), a press release indicated that, although no clinically significant safety issues were observed, no significant improvement in the primary endpoint, i.e. the composite score of the neuropsychological test battery RBANS-DMI, was observed at a dose of 25 mg (twice daily) in this clinical trial (<https://www.shionogi.com/global/en/news/2020/05/20200526.html>). The absence of safety issues is in accordance with recent studies looking into the role of PDE4 subtypes in gastro-intestinal side effects associated with PDE4 inhibition. The Richter laboratory indicated that inhibition of more than one subtype will elicit specific side effects (i.e. gastroparesis and hypothermia) but that subtype-selective inhibition will not (Boyd et al., 2021; McDonough et al., 2020). Thus, the inability of meeting the primary endpoint in the Phase II trial using BPN14770 likely resulted, despite seeming target engagement (Wakabayashi et al., 2020), from a lack of efficacy rather than due

to adverse side effects. The question remains whether this lack of efficacy would be a compound-specific or mechanism-dependent effect.

Other PDE4D-selective compounds have been developed and are reported to enhance neuroplasticity and memory processes (e.g., V11294, GEBR7b and GEBR32a)(Brullo et al., 2014; Brullo et al., 2016; Bruno et al., 2011; Cavalloro et al., 2020; Gale et al., 2003; Gale et al., 2002; Prosdocimi et al., 2018; Ricciarelli et al., 2017)(**Chapter 4**). It still remains to be determined whether different classes of molecules will show efficacy without side effects in clinical trials. Nevertheless, in preclinical studies, GEBR32a did not induce emetic-like behavior for doses 1000-fold higher than the memory-enhancing dose (Ricciarelli et al., 2017). Compound-specific effects could involve suboptimal dosing regimens, while mechanism-dependent effects may relate to the inability of UCR2-engaging long form PDE4(D) inhibitors to achieve full inhibition as outlined above. Importantly, different classes of PDE4(D) inhibitors may have additional PDE4(D)-independent actions based on their specific pharmacophores.

Interestingly, GEBR32a shows structural similarities to the clinically used anti-Alzheimer drug donepezil. Donepezil is regarded mainly as an acetylcholinesterase inhibitor but it also acts a potent agonist of the  $\sigma_1$ -receptor (Ishikawa et al., 2009; Solntseva et al., 2014). Moreover, the structural resemblance between donepezil and GEBR32a is also seen for the selective  $\sigma_1$ -receptor agonist SA4503 or cutamesine (**Figure 1A**). Based on this structural similarity, GEBR32a may, like donepezil and SA4503, bind  $\sigma_1$ -receptors. Molecular docking of GEBR32a, donepezil, and SA4503 in a crystal structure of the  $\sigma_1$ -receptor reveals a potential similar binding mode for all three compounds (**Figure 1B-C**). Interestingly, a central nitrogen atom that is reported to be crucial for  $\sigma_1$ -receptor binding is present in each compound and (almost) overlays (Bolshakova et al., 2016). Intriguingly, GEBR32a's memory-enhancing effects may thus be due to PDE4(D) inhibition and potentially additional effects such as  $\sigma_1$ -receptor activation. Agonism of the  $\sigma_1$ -receptor by donepezil and

SA4503 can promote neurite outgrowth (Ishima et al., 2008; Li et al., 2017); observations that were also described in **Chapter 4** for GEBR32a. Thus, while still speculative and to be investigated, the neuronal plasticity enhancement by GEBR32a may, in addition to its inhibitory effect on PDE4(D), be induced by activation of  $\sigma_1$ -receptor.

**Figure 1. Structural comparison of GEBR32a with  $\sigma_1$ -receptor agonists.** A) Chemical structures of SA4503 (cutamesine), donepezil and GEBR32a with their 3,4-dialkoxyphenyl moiety indicated in the orange square. B) Binding poses of GEBR32a (purple) and donepezil (pink) in a crystal structure of the  $\sigma_1$ -receptor based on molecular docking. Striking is the overlay of the rings of both GEBR32a and donepezil and close proximity of the central nitrogen atom. C) Binding poses of GEBR32a (purple) and SA4503/cutamesine (pink). Striking is the overlay of the central nitrogen atom and rings of both GEBR32a and SA4503.

### Considering the effects of PDE4D inhibition in different brain regions

In general, while the role of PDE4(D) in neuroplasticity processes has been reported in a substantial amount of scientific literature as mentioned above, its effects on human cognition, and especially in an AD context, has not been thoroughly explored. A possible explanation of the relative lack of efficacy of BPN14770 in AD is the fact that global PDE4D inhibition in multiple brain regions simultaneously may have less potent cognition-enhancing effects than local PDE4D

inhibition in, for example, the hippocampus specifically. Linked to this, the work of the Arnsten laboratory has indicated that PDE4D expression during aging in the frontal cortex of rats actually decreases, which is concurrent with increased phosphorylation of tau protein, which could promote AD-associated pathology, and worsen working memory (Leslie et al., 2020). Consequently, in elderly subjects, PDE4D inhibition may improve hippocampus-dependent memory processes while impairing frontal cortex-based functions like working memory. Importantly, across different brain regions, intracellular localization of PDE4D and its isoforms may be differentially regulated. For example, PDE4D can localize presynaptically at hippocampal pyramidal neurons (Montenegro-Venegas et al., 2022), whilst PDE4D is localized predominantly postsynaptically, at pyramidal neurons in the prefrontal cortex (Datta et al., 2020). The region-specific localization of PDE4D may result from a difference in expression of PDE4D-binding partner proteins (as summarized in **Chapter 2**) across regions. PDE4D may be localized presynaptically to modulate cAMP levels that regulate plasticity-promoting hyperpolarization-activated cation channel signaling (Beaumont and Zucker, 2000), while postsynaptic PDE4D can modulate synaptic plasticity through, for example, cAMP-PKA-CREB signaling (Kandel, 2012). Thus, PDE4D inhibition may have to be regional to exert sufficiently potent therapeutic effects.

Different strategies can be explored to achieve this increased spatial specificity. Firstly, assuming most memory-enhancing effects of PDE4D inhibition are exerted in the hippocampus, PDE4D isoforms that are specifically enriched in this brain region could be targeted. For example, **Chapter 4** described that PDE4D8 is highly expressed in the mouse hippocampus, but not in the frontal cortex, nor in the mouse neuronal HT22 cell line. As such, its hippocampal expression may be a result of expression in non-neuronal cell types. Whether targeting PDE4D8 could provide a means to establish hippocampus-specific and plasticity-enhancing PDE4D inhibition remains to be determined. As described above, it is possible to develop

inhibitors that exploit binding to conformational states that are specific to long isoforms but targeting one long isoform specifically (e.g., PDE4D8) cannot be achieved using this rationale. Interestingly, the highly localized cAMP-hydrolyzing actions of specific PDE4D isoforms can be deregulated by means of disrupting protein-protein interactions of the specific isoform and its partner protein(s) (Baillie et al., 2019; Lee et al., 2013). The potential of this approach has been demonstrated *in vivo* as well (Martin et al., 2014). However, the interactome of distinct PDE4D isoforms is currently incomplete and partner proteins may be cell type-specific and context-specific. Thus, while providing high spatial specificity within cells, the precise interaction that is to be disrupted remains to be verified.

Secondly, increased spatial specificity of pharmacological targeting can be achieved by using synergistic interventions that both act on regionally expressed targets. More concretely, the synergism of two treatments minimizes the induction of side effects by one of the treatments in 'off-target areas' as, owing to the synergism, lower concentrations for each of the treatments are required. Consequently, effects are conditional on both targets being expressed in the brain region where therapeutic effects should be elicited.

### **Synergistic PDE inhibition to achieve more localized therapeutic effects without side effects**

The concept of synergistic PDE inhibition to promote neuronal plasticity and memory consolidation was described in **Chapter 6**. Here, the synergistic effects of PDE4 and PDE2 inhibition in neuronal plasticity processes *in vitro* and memory consolidation *in vivo* were validated (Paes et al., 2020b). While these data robustly show that synergistic PDE4 and PDE2 inhibition can improve memory processes, the ability to translate *in vitro* to *in vivo* findings in these type of studies should be addressed. Specifically, the potential mismatch between inhibitor concentrations and doses used in *in vitro* and *in vivo* assays, respectively, requires discussion. In **Chapter**

**6**, the half-maximum inhibitory concentrations ( $IC_{50}$ ) of the PDE4 inhibitor roflumilast and PDE2 inhibitor PF-05180999 are reported to be 0.234 nM and 0.440 nM respectively, while the 1  $\mu$ M concentrations used to investigate AMPA receptor GluR1 subunit phosphorylation in brain slices were >2000-fold higher.

This apparent discrepancy in functional concentrations can be attributed to several factors. Firstly, the reported  $IC_{50}$  values usually are reported on the compound's ability to inhibit the activity of purified enzymes rather than enzymes in a cell context. As outlined in **Chapter 2** and summarized in that chapter's **Table 1**, several post-translational modifications and protein partner interactions can influence PDE4 enzyme activity and inhibitor affinity (Paes et al., 2021). Since these modifications and interactors are not present in inhibitor affinity assays using purified enzymes, these assays cannot accurately reflect affinities of PDE4 inhibitors in cells. Moreover, the purified PDE4 that is used in these assays often comprises a single PDE4 subtype and often only considers the PDE4 catalytic domain. As elaborately outlined in **Tables 2-4 of Chapter 2**, PDE4 inhibitors can exhibit distinct affinities towards different PDE4 subtypes and especially show different binding to full-length enzymes compared to catalytic domains only (Paes et al., 2021). Abovementioned arguments are supported by experimental evidence as described by Wunder and colleagues (Wunder et al., 2013). In their study, it was found that  $IC_{50}$  values for roflumilast were 89-fold higher in cell-based assays compared to  $IC_{50}$  values determined using purified enzymes. Similar observations were done for other PDE4 inhibitors. Interestingly, the ratio between cellular and purified enzyme  $IC_{50}$  values seems to depend on the binding modes of PDE4 inhibitors in the catalytic domain as the conformation-dependent, UCR2-engaging PDE4 inhibitors tested actually show lower  $IC_{50}$  values in cells compared to purified enzymes. This suggests that PDE4 enzymes may adopt distinct conformations in the different assays which can favor binding of either UCR2-engaging or purely catalytic domain-binding inhibitors. Secondly, although relatively high concentrations have been applied

extracellularly, functional concentrations in the relevant intracellular PDE2 and PDE4 signaling microdomains may be lower depending on cell penetrance and intracellular diffusion. Thirdly, it is important to consider the specific experimental setup and its associated cellular signaling when determining PDE4 inhibitor concentrations that induce a particular effect. For the experiments using brain slices described in **Chapter 6**, cAMP signaling was not promoted by any exogenous trigger (e.g. cAMP synthesis stimulation by forskolin). Thus, in the absence of high levels of cAMP, their breakdown can also not be prevented by inhibition of PDE2 and/or PDE4. In order to elicit cellular effects downstream of cAMP-PKA signaling in the absence of signals triggering this cascade, profound inhibition of PDE2 and PDE4 is required to elevate basal cAMP levels. This would require higher levels of the corresponding inhibitors. However, as indicated by the cell-based experiments in **Chapter 6**, in the absence of forskolin, even relatively high concentrations of roflumilast and/or PF-05180999 (i.e. 1  $\mu$ M) could not significantly stimulate CRE-mediated transcription. Lastly, despite the use of relatively high concentrations of roflumilast and/or PF-05180999, conclusions on the involved mechanisms can still be drawn as long as the selectivity of their inhibition can be guaranteed. Encouragingly, roflumilast and PF-05180999 exhibit >1000-fold selective binding towards respectively PDE4 and PDE2 compared to other PDE families (Hatzelmann et al., 2010; Helal et al., 2017). It is therefore unlikely that these compounds exerted effects through other targets than PDE4 and PDE2.

While the abovementioned factors can help explain the discrepancy between the  $IC_{50}$  values of roflumilast and PF-05180999 and the functional concentrations required to elicit effects in cells, the translation of  $IC_{50}$  values to therapeutic doses *in vivo* is even more complex. Taking into account the ability of roflumilast and PF-05180999 to be bound to plasma albumin and their brain penetrance, it is obvious that  $IC_{50}$  values derived from enzyme kinetic assays cannot accurately be extrapolated to *in vivo* settings. *In vivo*, a compound's net effect will also be

dependent on its affinity towards different isoforms and the relative expression ratio of these isoforms in the cells that are to be targeted. Moreover, determining free fractions of inhibitors in the brain may not reflect the compound concentration that is able to bind targets, but may rather reflect the compound concentration that is not (yet) bound to the target.

Thus, taking into account the difficulties in translating functional *in vitro* compound concentrations to *in vivo* doses, assays should be performed at the enzyme, cell, brain region, and organism level to properly validate the therapeutic potential of a treatment strategy. The studies described in **Chapter 6** robustly showed that PDE4 and PDE2 inhibition using suboptimal doses for each compound acts synergistically to promote cellular neuroplasticity processes and memory consolidation. The potential of synergistically acting treatments is supported by the pro-cognitive effects of synergistic PDE4 and PDE5 inhibition as reported by Gulisano and co-workers (Gulisano et al., 2018). As PDEs from different gene families show different intracellular distribution patterns, relatively subtle inhibition of two different types (e.g., PDE4 and PDE2 or PDE4 and PDE5) may promote a broader and/or prolonged cAMP diffusion in the cells to elicit downstream signaling responses. While the memory-enhancing effects of combined PDE4 and PDE5 inhibition have been validated after chronic treatment in a transgenic AD model (Gulisano et al., 2018), the synergistic actions of PDE4 and PDE2 inhibition presented here were only investigated upon acute exposure in wild-type mice. Thus, it remains to be verified whether these acute effects can be extrapolated to chronic treatments in an AD context.

### **Looking ahead**

In light of the findings and conclusions described above, future experiments and “backup plans” can be devised. Important next steps would be to determine what the effects are of chronic knockdown of PDE4D (long) isoforms on neuronal

plasticity and whether knockdown of multiple (long) PDE4D isoforms has additive effects. Crucial would be the comparison of cell-type specific, region-specific and brain-general PDE4D knockdown and elucidating which PDE4D isoforms are involved in side effects mediated by either the brainstem and/or gastrointestinal organs. The function and intracellular localization of individual isoforms in specific cell types could be investigated using isoform knockdown or dominant-negative PDE4 isoforms coupled with the use of FRET-based cAMP sensors to determine isoform-regulated cAMP nanodomains (Bock et al., 2020; Bolger et al., 2020). These experiments should provide additional insights into the PDE4D isoforms that should be targeted for a more efficacious and/or safer treatment. While both strategies outlined in the thesis (i.e. more specific targeting of PDE4 subtypes or isoforms and synergistic inhibition of PDE4 and another PDE type) can be investigated further to treat memory problems in AD, additional promise could lay in combining these strategies. This would mean that a PDE4 inhibitor specific towards certain subtypes/isoforms (e.g., the PDE4D-selective inhibitor GEBR32a) can be combined with an inhibitor of another PDE type (e.g., the PDE2 inhibitor PF-05180999). This combination will minimize off-target effects by using a more selective PDE4 inhibitor and, owing to the synergistic actions, lower doses of each inhibitor are required, which will minimize the occurrence of side effects. Although it is to be expected, it remains to be validated experimentally whether synergistically acting treatments are less likely to evoke side effects. In addition to combining two PDE-inhibiting compounds that have synergistic actions, single molecules can be explored further that have dual actions on PDE4 and another target. For example, molecules have been described that can inhibit both PDE4 and acetylcholinesterase (AChE) enzymes (Liu et al., 2022). As most of the clinically used AD medication belongs to the class of AChE inhibitors (i.e. donepezil, galantamine, and rivastigmine; see **Chapter 1**), therapeutic effects of dual PDE4/AChE are to be expected. Dual PDE4/AChE inhibitors can potentially increase intracellular cAMP signaling by simultaneously elevating

extracellular acetylcholine levels, which can promote cAMP synthesis, and inhibiting PDE4-mediated cAMP breakdown. This synergistic mechanism may require lower doses, which could translate to a lower likelihood of side effects. It is interesting to envision drug development/optimization efforts of dual PDE4/AChE inhibitors to achieve PDE4 subtype selectivity while retaining AChE inhibitory actions. Importantly, as the use of AChE inhibitors is associated with side effects that overlap with those observed for PDE4 inhibitors (i.e. nausea, emesis, diarrhea) (Imbimbo, 2001), the safety of dual PDE4/AChE inhibitors should be examined.

Generally, side effects associated with the use of PDE4 inhibitors are arguably the main reason PDE4 inhibitors are not yet clinically used for the treatment of AD. Thus, efforts should be taken to minimize or prevent PDE4-mediated side effects. Next to the approaches undertaken in this thesis, other strategies can be further explored to reduce side effects. By formulating the prototypical PDE4 inhibitor rolipram with fusogenic lipid vesicles, Gobejishvili et al. decreased rolipram's ability to cross the blood-brain barrier, which was concurrent with a reduction in emetic-like behavior in mice (Gobejishvili et al., 2022). Since therapeutic actions of PDE4 inhibitors are required in the brain as well, this strategy cannot be pursued for the treatment of AD. Interestingly, the PDE4 inhibitor LEO-29102 has low emetic potential and was designed as a 'soft drug', which means that it creates few, long-lasting, metabolites (Felding et al., 2014). LEO-29102, formulated as a cream, has been tested in a Phase II clinical trial for the treatment of atopic dermatitis [NCT01037881]. It remains to be determined whether the low emetogenicity of LEO-29102 is related to the route of administration and whether administration routes that optimize brain exposure would not result in side effects, despite the rapid metabolism of the compound. Furthermore, LEO-29102 interacts with amino acids in the C-terminus of PDE4 that are conserved across PDE4 subtypes as opposed to PDE4(D) long-form, UCR2-engaging inhibitors that have shown to be efficacious in

stimulating neuroplasticity. Thus, considering its different binding mode, its subtype-selectivity and efficacy await to be examined.

As recent reports by the Richter laboratory have indicated that subtype-selective PDE4 inhibition can prevent certain PDE4-mediated side effects, subtype-specific inhibition rather than PDE4D-selective inhibition may be sufficient to reduce side effects. While inhibition of PDE4D rather than PDE4B seems to exert the most profound memory-enhancing effects (Zhang et al., 2017), the precise role of non-PDE4D subtypes and isoforms in molecular memory mechanisms that are affected in AD remain to be fully explored experimentally. Similarly, PDE4 is not the only cAMP-selective PDE. Provided the pivotal role of cAMP-PKA-CREB signaling in memory formation, other cAMP-selective PDEs and their isoforms provide novel therapeutic targets. As a proof-of-principle, we have shown that PDE7 inhibition also promotes spatial memory consolidation (McQuown et al., 2021). Thus, the same target-specifying strategies as described in this thesis can be applied to other cAMP-modulating therapeutic targets.

All in all, the work in this thesis shows that more specific targeting of PDE4D isoforms can retain the therapeutic neuroplasticity-enhancing effects that are observed upon non-selective PDE4(D) inhibition. Moreover, synergistic inhibition of PDE4 and PDE2 shows therapeutic potential and likely reduces side effects as lower doses of each of the inhibitors are required. Thus, new strategies have been validated that provide new avenues to optimize PDE4-inhibiting strategies with improved efficacy and/or safety for the treatment of memory deficits in AD.

# Chapter 8

## Summary

The goals of this thesis were 1) to identify which PDE4D isoforms are involved in neuroplasticity processes that are impaired by AD-associated pathology, and 2) to investigate the therapeutic potential of using combined treatments to reduce the therapeutic dose of PDE4(D) inhibitors. In light of these goals, this thesis presents a comprehensive literature review and four experimental studies using *in silico*, *in vitro*, and *in vivo* approaches.

In order to identify which PDE4D isoforms are involved in neuroplasticity processes that are impaired by AD-associated pathology, an extensive overview was established on the molecular biology of PDE4 enzymes and their utility as pharmacological targets in **Chapter 2**. It was outlined that PDE4 enzymes are encoded by four different genes (*PDE4A-D*) that each give rise to multiple isoforms owing to the use of alternative promoters and alternative splicing. Confusion can arise when referring to these isoforms as their nomenclature may differ across online databases, species and depending on whether one refers to the isoform's mRNA or protein. Hence, an overview figure of all known isoforms (page 41) and a comparison of human and rodent isoforms (page 126) were established to clarify the nomenclature and classification to the scientific field and to easily refer to the multitude of isoforms in upcoming chapters. This chapter also summarized how differences in protein sequence across PDE4 subtypes and isoforms result in different properties in view of enzymatic activity regulation, protein-protein interactions and inhibitor binding by changing the enzyme's conformation. The amino acids involved in all reported post-translational modifications and interactions with other proteins were illustrated in an overview figure (page 51). Moreover, the effect of these modifications and interactions on enzymatic activity of PDE4 subtypes or isoforms and their affinity to PDE4 inhibitors was reported. This overview provided the rationale to establish a thorough analysis of the approaches to determine affinities of PDE4 inhibitors. Therefore, a comprehensive list of PDE4 inhibitors was compiled indicating affinity per PDE4 subtype (page 69), isoform (page 75) or conformation

(page 79). Lastly, potential mechanisms underlying the adverse side effects associated with PDE4 inhibition were described in relation to the therapeutic dose ranges of several PDE4 inhibitors.

Next, using the gained knowledge on human PDE4D isoform sequences, promoter DNA (hydroxy)methylation and mRNA expression of PDE4D isoforms were measured in post-mortem material of the middle temporal lobe of AD patients and healthy controls (**Chapter 3**). Specific isoforms (PDE4D1, -D3, -D5, and -D8) displaying increased expression in AD were identified, concomitant with changes in the DNA methylation signatures of associated promoter regions. Moreover, increased PDE4D1 and PDE4D3 expression was associated with higher levels of plaque and tangles and lower cognitive performance. This study indicated that, although stemming from the same gene, expression regulation of PDE4D is impacted in an isoform-specific manner in AD.

To follow up on and complement these findings using human material, studies using animal models and cell lines were conducted in **Chapter 4**. In correspondence to the observations in human tissue, an upregulation of the same PDE4D isoforms was found in brain material of transgenic AD mice that exhibit amyloid- $\beta$  pathology as well as in cultured hippocampal neurons exposed to amyloid- $\beta$ . The notion that pharmacological PDE4D inhibition can promote neuronal plasticity was validated in the same mouse hippocampal neuronal cell line. Making use of CRISPR-Cas9 mediated gene-editing, it was determined in the same cell line that specific knockdown of one of the long PDE4D isoforms (i.e. PDE4D3, PDE4D5, PDE4D7, and PDE4D9) is sufficient to enhance neuronal plasticity processes. Moreover, knockdown of one of these isoforms could protect against plasticity-impairing effect of amyloid- $\beta$ . Lastly, this chapter indicated which of the long PDE4D isoforms may not be involved in stomach-associated side effects of PDE4(D) inhibition by describing the isoform-specific expression in the mouse stomach.

Since knockdown of long-form PDE4D isoforms specifically was found to promote neuronal plasticity, the understanding of the molecular biology of the different PDE4D isoforms described in **Chapter 2** could be used to put these findings into a mechanistic perspective. The enzyme activity of PDE4D isoforms is differentially altered by phosphorylation by protein kinase A (PKA) and/or extracellular signal-regulated kinase (ERK) depending on the isoform category (i.e. long, short, and supershort). In order to understand why genetic knockdown of long isoforms specifically enhanced neuronal plasticity, an *in silico* computational model was established to simulate how the different isoform categories regulate cyclic adenosine monophosphate (cAMP) levels and control downstream signaling over time (**Chapter 5**). Here, it was described that long PDE4D isoforms specifically exert the largest control on cAMP and its downstream signaling. Hence, supporting the experimental data of the previous chapter, inhibition of long PDE4D isoforms may provide the most profound approach to increase cAMP signaling involved in neuronal plasticity processes.

In view of the first goal of this thesis, inhibition of specific PDE4D isoforms involved in (AD-associated) memory processes could provide a more efficacious and/or safer therapeutic strategy. Besides this approach, the safety of PDE4(D) inhibitors can be improved by lowering the required therapeutic dose to reduce the risk of adverse side effects. Following up on the second goal of this thesis, **Chapter 6** demonstrates the potential of combining PDE2 and PDE4 inhibitors to promote neuroplasticity *in vitro* and stimulate memory consolidation *in vivo*. As it was found that PDE2 and PDE4 inhibitors exert synergistic actions, the therapeutic doses of each inhibitor could be lowered, which would minimize the risk of PDE4-mediated adverse side effects.

Concludingly, the work in this thesis has established the potential of PDE4D isoform-specific inhibition and synergistic PDE4/PDE2 inhibition as new strategies to

make PDE4-targeting therapies more efficacious and/or safer for the benefit of treating memory deficits in AD.

# Chapter 9

## Samenvatting

De doelstellingen van deze thesis waren 1) het identificeren welke PDE4D-isovormen betrokken zijn bij de processen van neuroplasticiteit die door AD-gerelateerde pathologie aangedaan worden, en 2) het onderzoeken van het therapeutische potentieel van gecombineerde behandelingen gericht op het verlagen van de therapeutische dosis van PDE4(D)-inhibitoren. In het kader van deze doelstellingen worden in deze thesis een uitgebreide literatuurreview uiteengezet, alsmede vier experimentele studies waarin gebruik is gemaakt van *in silico*, *in vitro* en *in vivo*-methoden.

Om te kunnen identificeren welke PDE4D-isovormen betrokken zijn bij de processen van neuroplasticiteit die aangetast worden door AD-gerelateerde pathologie, wordt in **Hoofdstuk 2** een uitgebreid overzicht gepresenteerd die de moleculaire biologie van PDE4-enzymen uiteenzet en het potentieel van deze enzymen als effectief farmacologisch doelwit. In dit hoofdstuk wordt beschreven dat PDE4-enzymen door vier verschillende genen worden gecodeerd (*PDE4A-D*) die elk, door middel van alternatieve promoters en alternatieve splicing, meerdere isovormen tot expressie kunnen brengen. Bij het refereren naar deze isovormen kan er onduidelijkheid ontstaan doordat er verschillen bestaan in de gebruikte nomenclatuur binnen online databases, binnen diersoorten en of er wordt gerefereerd naar het mRNA of het eiwit van de isoform. Derhalve is een overzicht van alle tot dusver bekende isovormen samengesteld (pagina 41) samen met een vergelijking van humane isovormen en isovormen bij knaagdieren (pagina 126) ter verduidelijking van de nomenclatuur en classificatie voor het wetenschappelijke veld en om makkelijker te kunnen refereren naar de veelvuldige isovormen in de volgende hoofdstukken. In dit hoofdstuk wordt ook samengevat hoe verschillen in eiwitsequentie tussen PDE4-subtypen en -isovormen leiden tot verschillende eigenschappen met betrekking tot regulatie van enzymactiviteit, eiwit-eiwitinteracties en het binden van inhibitoren door veranderingen in de conformatie van het enzym. Welke aminozuren betrokken zijn bij alle in de literatuur beschreven

post-translationele modificaties en interacties met andere eiwitten is weergegeven in de figuur op pagina 51. Eveneens wordt het effect van deze modificaties en interacties op enzymatische activiteit van PDE4-subtypen of -isovormen en PDE4-inhibitoraffiniteit beschreven. Dit overzicht heeft de aanleiding gevormd om een grondige analyse uit te voeren naar de wijze waarop de affiniteit van een PDE4-inhibitor wordt bepaald. Daartoe is een uitgebreid overzicht van PDE4-inhibitoren samengesteld waarbij affiniteit wordt weergegeven per PDE4-subtype (pagina 69), isovorm (pagina 75) en conformatie (pagina 79). Tenslotte worden de potentiële onderliggende mechanismen beschreven die geassocieerd worden met de negatieve bijwerkingen door PDE4-inhibitie en hoe deze zich verhouden tot therapeutische doses van verscheidene PDE4-inhibitoren.

Vervolgens, gebruikmakend van de opgedane inzichten omtrent humane PDE4D isovorm sequenties, werden promotor DNA (hydroxy)methylatie en mRNA expressie van PDE4D isovormen gemeten in post-mortem hersenmateriaal van de middelste slaapwending van AD patiënten en gezonde controles (**Hoofdstuk 3**). Specifieke isovormen (PDE4D1, -D3, -D5 en -D8) werden geïdentificeerd die een verhoogde expressie in AD lieten zien, welke geassocieerd was met veranderingen in het DNA methylatieprofiel van de corresponderende promotor-regio's. Bovendien was verhoogde PDE4D1 en PDE4D3 expressie geassocieerd met verhoogde niveaus van amyloïde plaques en neurofibrillaire tangles en een lager cognitief vermogen. Deze studie toonde aan dat, hoewel isovormen voortkomen uit hetzelfde gen, expressieregulatie van PDE4D in AD wordt beïnvloed op een isovorm-specifieke wijze.

Om voort te borduren op de gedane bevindingen in humaan materiaal en deze bevindingen aan te vullen werden er in **Hoofdstuk 4** experimenten verricht gebruikmakend van diermodellen en cellijnen. In overeenstemming met de observaties in human weefsel werd er een expressieverhoging van dezelfde PDE4D isovormen gevonden in hersenmateriaal van transgene AD muizen die  $\beta$ -amyloïd

pathologie vertonen alsmede in gekweekte hippocampale neuronen blootgesteld aan  $\beta$ -amyloïd. Het idee dat farmacologische inhibitie van PDE4D neuronale plasticiteit kan bevorderen werd gevalideerd in dezelfde muriene hippocampale neuroncellijn. Gebruikmakend van CRISPR-Cas9 gemedieerde genbewerking werd in dezelfde cellijn bepaald dat specifieke knock-down van één van de lange PDE4D isovormen (i.e. PDE4D3, PDE4D5, PDE4D7 en PDE4D9) voldoende is om neuronale plasticiteitsprocessen te verbeteren. Bovendien kon knock-down van één van deze isovormen bescherming verschaffen tegen het plasticiteit-aantastende effect van  $\beta$ -amyloïd. Ten slotte gaf dit hoofdstuk, door het beschrijven van isovorm-specifieke expressie in de muizenmaag, aan welke van de lange PDE4D isovormen wellicht niet betrokken zijn bij het induceren van maag-geassocieerde bijwerkingen van PDE4(D) inhibitie.

Aangezien het werd gevonden dat knock-down van lange PDE4D isovormen neuronale plasticiteit bevordert, kon het inzicht in de moleculaire biologie van de verschillende PDE4D isovormen zoals beschreven in **Hoofdstuk 2** gebruikt worden om deze bevindingen in een mechanistisch perspectief te plaatsen. De enzymactiviteit van PDE4D isovormen wordt differentieel beïnvloed door fosforylering door 'proteïn kinase A' (PKA) en/of 'extracellulair signaal-reguleerde kinase' (ERK) afhankelijk van de isovorm-categorie (i.e. lang, kort en superkort). Om te begrijpen waarom genetische knock-down van specifiek lange isovormen neuronale plasticiteit bevorderde, werd er een *in silico* computationeel model gecreëerd om te simuleren hoe de verschillende isovorm-categorieën cyclisch adenosine monofosfaat (cAMP) niveaus reguleren en hoe deze de vervolgsignalering beïnvloeden gedurende de tijd (**Hoofdstuk 5**). In dit hoofdstuk werd beschreven dat specifiek lange PDE4D isovormen het grootste effect uitoefenen op cAMP signalering en de signalering die daarop volgt. De experimentele data uit het vorige hoofdstuk wordt hierdoor ondersteund en daardoor kan gesuggereerd worden dat

inhibitie van lange PDE4D isovormen de meest effectieve aanpak is om de cAMP signalering die betrokken is in neuronale plasticiteitsprocessen te bevorderen.

Betreffende de eerste doelstelling van deze thesis kan inhibitie van specifieke PDE4D isovormen betrokken bij (AD-geassocieerde) geheugenprocessen een effectievere en/of veiligere behandelstrategie verschaffen. Naast deze aanpak kan de veiligheid van PDE4(D) inhibitoren ook verbeterd worden door het verlagen van de therapeutische dosis om het risico op nadelige bijwerkingen te reduceren. In lijn met de tweede doelstelling van deze thesis, laat **Hoofdstuk 6** het potentieel zien van het combineren van PDE2 en PDE4 inhibitoren om neuroplasticiteit *in vitro* en geheugenvorming *in vivo* te stimuleren. Aangezien werd bevonden dat PDE2 en PDE4 synergistische acties vertonen, zouden therapeutische doses van iedere inhibitor verlaagd kunnen worden wat er vervolgens voor zou kunnen zorgen dat het risico op PDE4-gemedieerde nadelige bijwerkingen geminimaliseerd wordt.

Concluderend, het werk in deze thesis heeft de potentie van PDE4D isovorm-specifieke inhibitie en synergistische PDE4/PDE2 inhibitie vastgesteld als nieuwe strategieën om behandelingen gericht op PDE4 doeltreffender en/of veiliger te maken ten bate van de behandeling van geheugenproblemen in AD.

# Appendix

**Impact Paragraph**

## Scientific impact

An increasing prevalence of Alzheimer's disease (AD) has greatly stimulated the urge to increase the amount of more and better treatments. However, the progression to the clinic of pharmacological treatments that treat memory problems associated with AD has stagnated since the development of acetylcholinesterase inhibitors (i.e., rivastigmine, galantamine, and donepezil) and memantine. Although the drug aducanumab was recently approved by the Food and Drug Administration (FDA), yet rejected by the European Medicines Agency (EMA), the severe adverse effects associated with this treatment has caused a lot of controversy. Therefore, the efficacy and safety of aducanumab remain to be better defined. In general, the efficacy and safety of current AD medication can be regarded as suboptimal as therapeutic actions are often short lasting, patient-specific and/or concurrent with adverse effects like headaches, nausea, vomiting, and diarrhea. Thus, there is an urgent need for new pharmacological treatment strategies to combat AD-associated memory problems.

As outlined in this thesis, insights into the molecular biology of PDE4 as pharmacological target opens up avenues to improve PDE4-targeting therapies for the treatment of Alzheimer's disease (AD). While the potential of PDE4 inhibition to stimulate memory consolidation has been studied extensively, adverse side effects associated with PDE4 inhibition required this treatment strategy to become more specific. Since the PDE4 enzyme family comprises several subtypes and isoforms (**Chapter 2**), target specification can be performed in order to make PDE4-targeting therapeutic more efficacious and/or safer. From a scientific perspective, the work in this thesis has provided the insight that long PDE4D isoforms in particular are involved in the regulation of neuronal plasticity, also in presence of AD-associated pathology. This insight has implications for the design and development of PDE4 inhibitors, which can eventually translate into pharmacological treatments for memory problems in AD patients. Since long isoforms can adopt distinct conformational states compared to (super)short isoforms and PDE4D expresses

subtype-unique amino acids, PDE4 inhibitors can be developed that exploit these features to obtain long PDE4D isoform binding specificity. Since potential PDE4 inhibitors are often solely screened for their affinity of binding the PDE4 catalytic domain rather than affinity towards specific PDE4 subtype and/or isoforms (**Chapter 2**), many small molecules may have been disregarded as lowly potent inhibitors whilst they may actually be able to selectively bind certain subtype or isoform specific conformations. Thus, since targeting specific subtypes or isoforms may be therapeutically more efficacious or safer, potential subtype-selectively or conformation-selectivity of (disregarded) PDE4 inhibitors may have to be reconsidered.

Accordingly, based on a molecular docking screening approach, the ability of PDE4 inhibitors (n=3013) to bind different PDE4 subtypes and conformations was modeled. In **Figure 1**, the affinity of these inhibitors towards the PDE4D catalytic domain and PDE4D catalytic domain with its C-terminus capped is shown, indicating that certain inhibitors bind with higher affinity to C-terminus capped conformations. Thus, based on the insights from this thesis that certain isoforms provide a more promising therapeutic target than others, PDE4 inhibitors can be selected or designed to selectively bind the isoform of interest. A preliminary selection of inhibitors could be based on *in silico* screenings, as exemplified here, to provide multiple small molecules that can be tested and validated as subtype-specific or isoform-specific PDE4 inhibitor to treat cognitive problems in AD.

In addition to a more precise targeting of PDE4 subtypes and isoforms, this thesis has provided a proof-of-principle set of experiments that highlight the therapeutic potential of the synergistic actions of PDE4 and PDE2 inhibition on memory consolidation processes (**Chapter 6**). Further characterization of the efficacy and safety of this treatment strategy in preclinical disease models and subsequent clinical studies may eventually lead to a clinically safe pharmacological intervention that can alleviate memory problems in patients suffering from AD.

**Figure 1.** Binding affinities of PDE4 inhibitors (n=3013) for PDE4D catalytic domain and PDE4D catalytic domain with the C-terminus capped based on molecular docking *in silico* screening using crystal structures of different PDE4D conformations available on RCSB Protein Data Bank.

Beyond AD, the principles of subtype/isoform specific PDE4 inhibition and synergistic PDE4 and PDE2 inhibition as therapeutic strategies has also implications for the research into PDE4 as a therapeutic target in other disorders. Since PDE4-mediated cAMP signaling occurs in any cell type, PDE4 enzymes provide interesting targets in a myriad of diseases. Since PDE4 inhibitors, depending on administration route and dose, can be associated with severe adverse effects, target specification towards PDE4 subtypes and/or isoforms is key to optimize efficacy and safety. Thus, similar approaches as taken to optimize PDE4 inhibition to treat AD as delineated in this thesis, could, and perhaps should, be applied to other diseases in which PDE4 inhibition has shown promise. In **Table 1**, several illustrative disorders are listed for which PDE4-targeting treatment strategies could be optimized by means of target specification.

**Table 1.** Illustrative list of diseases that may benefit from PDE4 target specification.

Type of condition	Disease	Reference
<b>Neurological</b>	Parkinson's disease	(Chen et al., 2022; Dong et al., 2021)
	Multiple Sclerosis	(Scheppers et al., 2019)
	(Ischemic) stroke	(Cai et al., 2022; Kaur et al., 2022)
	Fragile X syndrome	(Berry-Kravis et al., 2021)
	Neuropathic pain	(Zhang et al., 2022)
<b>Dermatological</b>	Psoriasis	(Aljefri et al., 2022)
<b>Gastro-intestinal</b>	Inflammatory Bowel Syndrome	(Liu et al., 2022)
<b>Pulmonary</b>	Idiopathic Pulmonary Fibrosis	(Herrmann et al., 2022)
<b>Hepatic</b>	Non-alcoholic fatty liver disease	(Tao et al., 2022; Yu et al., 2021)
<b>Metabolic</b>	Obesity	(Irelan et al., 2022)
<b>Addictive</b>	Methamphetamine reinforcement	(Honeywell et al., 2022)
<b>Cancer</b>	Breast cancer	(Mukherjee et al., 2022)
	Prostate cancer	(Powers et al., 2015; Xie et al., 2021)

Considering the potential of improving therapeutic strategies for these disorders by targeting specific PDE4 isoforms as outlined in this thesis, identifying the PDE4 isoforms involved in each particular disease is crucial. Determining the most promising PDE4 subtype and/or isoform could be determined by testing subtype-specific and isoform-specific PDE4 inhibitors, but also through measuring PDE4 subtype and isoform expression in disease states, insight can be acquired about which subtypes/isoforms could provide the best therapeutic target. The classification and comparison of the different PDE4 subtypes and isoforms has brought the insight that each of the PDE4 genes displays a characteristic exon architecture (**Chapter 2**). Each PDE4 isoform can be distinguished by sequences coming from an isoform-unique exon. As described in **Chapter 3** and **Chapter 4**, disease-associated mRNA expression of PDE4 isoforms can be measured using qPCR primers that amplify sequences stemming from these isoform-specific exons. Since the isoform-specific exons and the associated sequences are known, this information can be used to extract PDE4 isoform-specific expression patterns from (freely accessible) online data repositories of exon array and RNAseq experiments. As these data are available for

many diseases/experimental designs, also those in which PDE4 inhibition may have therapeutic effects, target specification towards PDE4 subtypes and/or isoforms could be explored by re-analyzing these datasets at the isoform level. Exon array datasets are particularly suitable for this approach as the expression of isoform-specific exons will give a direct indication of the expression of the associated isoform. Given the distinct roles of specific PDE4 isoforms, it is crucial to measure expression differences at the isoform level as general PDE4 expression may 'dilute' and mask isoform-specific expression differences. As a proof of principle, several publicly available exon array datasets were re-analyzed to investigate PDE4 isoform expression differences. As an example, in **Figure 2** the PDE4 isoform-specific expression is shown as measured by means of exon array analysis in post-mortem material of the entorhinal cortex of AD patients and healthy controls (based on GEO accession ID: GSE26972, (Berson et al., 2012)).

**Figure 2.** Proof-of-principle indicating that knowledge of PDE4 isoform-specific sequences can be used to determine PDE4 isoform-specific expression by means of re-analyzing publicly available Exon Array datasets. Note that the expression of isoforms PDE4D1 and PDE4D2 cannot be specifically and reliably assessed using the specific exon array probes used in this dataset.

Overall, oriented towards AD, the major scientific implications of the work in this thesis are the validation of new avenues to treat memory problems in AD by means of more specific PDE4 inhibition at the level of PDE4D isoforms or combined treatment with a PDE4 and PDE2 inhibitor. More generally and rather focused on PDE4 as therapeutic targets, this thesis has provided several *in silico*, *in vitro*, and *in vivo* research strategies that can be utilized to optimize PDE4-targeting therapies in a multitude of diseases.

### **Societal impact**

The fundamental insights into the role of specific PDE4D isoforms in the regulation of neuronal plasticity processes will be of use in developing more efficacious and safer therapies to treat memory deficits in AD. Although there is a long trajectory ahead until the treatment strategies explored here are validated in a clinical setting, the societal impact of this thesis will be most evident upon the development of isoform-specific PDE4D inhibitors and/or the validation of synergistic PDE4-PDE2 inhibition. Upon validation, patients suffering from AD-associated memory problems can be effectively treated and by mitigating their symptoms, the quality of life of patients, their family and caretakers will be greatly improved. More generally, society as a whole will benefit from improved PDE4-mediating therapeutics, as AD-associated burden on the healthcare system will be alleviated. Similarly, as highlighted in the previous section, the scientific insights into PDE4's molecular biology can also improve the treatment of other diseases which will benefit many other patient populations and associated families and caretakers. Despite the fact that it is hard to predict whether the outlined treatment strategies will be validated in a clinical setting, the scientific advancements presented here are sought to provide hope to patients, their families, caretakers and contributors to funding agencies like Alzheimer Nederland, as it shows that new treatment strategies can be created but only await to be proven successful.

**Curriculum Vitae | About the author**

Dean Paes was born on the 8th of July 1993 in Geleen, the Netherlands. Growing up in Obbicht, he attended secondary school at the Gymnasium of Trevianum Scholengroep in Sittard. In this period, he also completed two academic courses (Evolution and Physiology) at the Open University in Heerlen. Upon graduating secondary school, Dean enrolled into the bachelor program Molecular Life Sciences at Maastricht University in 2011. During this program, he followed the MaRBL<sup>e</sup> honors program and performed an internship under the supervision of Dr. Nicole Leibold and Prof. dr. Daniël van den Hove before obtaining the Bachelor Degree in 2014. In September 2014, he started the two-year Research Master Fundamental Neuroscience at Maastricht University. As part of this research master, he conducted a research internship at HiQScreen Sàrl in Geneva, Switzerland. During this internship, Dean investigated nicotinic acetylcholine receptors as pharmacological targets under supervision of Prof. dr. Daniel Bertrand. The associated Research Master Degree was obtained in July 2016. Continuing research in neuropharmacology, he then started working as a research assistant in the department of Psychiatry and Neuropsychology at Maastricht University to study the effects of phosphodiesterase (PDE) inhibitors on memory performance in rats.

Upon obtaining a Kootstra Talent Fellowship from the Maastricht University Medical Centre, Dean began his PhD research to investigate the role of PDE4D isoforms as pharmacological targets in the treatment of Alzheimer's disease at Maastricht University and Hasselt University in June 2017. This work was performed under supervision of promotores Prof. dr. Daniël van den Hove (Maastricht University) and Dr. Tim Vanmierlo (Hasselt University) and co-promotor Prof. dr. Niels Hellings (Hasselt University). Next to the PhD research, he supervised research projects of more than 20 bachelor, (research) master and Erasmus exchange students. Dean has also been a PhD representative and member of the educational committee of the School for Mental Health and Neuroscience (MHeNS) at Maastricht University from 2017 up until 2021. From 2020 until 2021, he was also a PhD

representative of the European Graduate School of Neuroscience (EURON). During his PhD trajectory, he also (co-)organized local and international symposia within the framework of MHeNS and EURON. Moreover, Dean attended and presented at several (inter)national conferences and symposia (e.g. Dutch Neuroscience Meeting and Gordon Research Conference/Seminar). Looking for innovative ways to approach the research questions of his PhD research, Dean initiated several collaborations. By means of a Young European Research University Network (YERUN) mobility award, he visited the lab of Prof. Eduardo Eyras at Pompeu Fabra Universidad in Barcelona, Spain in 2018 to learn how to analyze whole exome sequencing and RNA-seq data. From 2019 onwards, these insights would later be used to start a collaboration with Dr. Lars Eijssen (Maastricht University) to measure PDE isoform-specific expression from publicly available datasets. Parallel to the main PhD project, Dean initiated *in silico* screening approaches to (re-)evaluate existing and new compound as PDE4 inhibitors. After the PhD project, Dean started working as a scientist at Mosa Meat, a pioneering company in the cultivated meat industry. Currently, as a senior scientist, he is applying his insights in pharmacology and molecular cell biology there to develop cost-efficient culture media.

Systemic multipotent adult progenitor cells improve long-term neurodevelopmental outcomes after preterm hypoxic-ischemic encephalopathy. *Behav Brain Res*. 2019 Apr 19;362:77-81. doi: 10.1016/j.bbr.2019.01.016.

Nelissen E, De Vry J, Antonides A, **Paes D**, Schepers M, van der Staay FJ, Prickaerts J, Vanmierlo T. Early-postnatal iron deficiency impacts plasticity in the dorsal and ventral hippocampus in piglets. *Int J Dev Neurosci*. 2017 Jun;59:47-51. doi: 10.1016/j.ijdevneu.2017.03.006.

## **Book chapters**

*Published:*

**Paes D**, van Hagen BTJ and Prickaerts J (2018) Chapter 3 - Object Novelty Memory Tests: Methods, Test Procedures and Measurements, in *Handbook of Behavioral Neuroscience* (Ennaceur A and de Souza Silva MA eds) pp 39-51, Elsevier.

*In press:*

**Paes D**, Altuntaş E, Mall E, Jackish L, Doğan A, Post M (2023) Chapter: Cell Nutrition and Growth Media, in *Technological and Scientific Foundations of Cellular Agriculture*, Elsevier.

Mall E, Andriessen V, Jackish L, Doğan A, **Paes D**, Altuntaş E, Post M (2023) Chapter: Introduction to Cultured Meat, in *Technological and Scientific Foundations of Cellular Agriculture*, Elsevier.
