

Behavioral and molecular consequences of a 'double-hit' challenge on the pathogenesis of mouse models of depression and amyotrophic lateral sclerosis (ALS)

Citation for published version (APA):

Trofimov, A. (2024). Behavioral and molecular consequences of a 'double-hit' challenge on the pathogenesis of mouse models of depression and amyotrophic lateral sclerosis (ALS). [Doctoral Thesis, Maastricht University]. Maastricht University. https://doi.org/10.26481/dis.20240205at

Document status and date: Published: 01/01/2024

DOI: 10.26481/dis.20240205at

Document Version: Publisher's PDF, also known as Version of record

Please check the document version of this publication:

• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.

• The final author version and the galley proof are versions of the publication after peer review.

• The final published version features the final layout of the paper including the volume, issue and page numbers.

Valorization

Relevance for society

Major depressive disorder (MDD) remains to be one of the most common neuropsychiatric disorders recognized among the top causes of health loss worldwide. The etiology of MDD is multifactorial and comprises both hereditary and environmental factors, including stressful and pro-A combination of disease-driven 'sterile' inflammatorv triggers. inflammation due to emotional stress or genetically-determined neurodegeneration and pathogen-induced inflammation is a common clinical situation. An interaction of various factors when combined may lead to an altered progression of pathological processes in the CNS, including possible exacerbation of neuropsychiatric outcomes. Investigation of molecular mechanisms of such interactions is necessary for better understanding of the factors influencing the onset and progression of MDD, which will be used for the development of therapeutic approaches. Additionally, the FUS[1-359]-tg mouse line used in this study can serve as a useful model to further explore the role of microglia and inflammation in the mechanisms of ALS/FTLD syndrome.

Target groups

Patients with specific etiological factors of neuropsychiatric disorders, such as abnormal HPA activity due to chronic stress or neurodegenerative processes, and systemic inflammation. The combination of both factors may exacerbate neuropsychiatric symptoms.

Activity / Products

My work has demonstrated that the use of anti-inflammatory treatments can be beneficial in the management of neuropsychiatric and neurodegenerative disorders. The exploitation of coxibs in the management of depressive-like syndrome can be such example, suggesting that this therapeutic approach needs further investigation and development.

Innovation

My work is innovative in terms of exploitation of animal models that mimic an interplay between etiological factors of neuropsychiatric disorders rather than use a single challenge. This approach is likely to result in more valid translational research, as a combination of various etiological factors for neuropsychiatric disorders with a systemic inflammation represent a common clinical situation, and an interaction between systemic inflammation and specific etiological factors of neuropsychiatric disorders can exacerbate their symptoms.

Implementation

The results of my research have been published in peer-reviewed international journals, presented at international conferences, and contributed to our understanding of the overlapping molecular mechanisms underlying depressive syndrome induced by emotional stress, neurodegeneration, and systemic inflammation.
