September 2009

Abstract

Recent empirical studies of firm-level performance have tested complementarity in the case of multiple practices. These papers have drawn conclusions using potentially biased estimates of pair-wise interaction effects. We develop a consistent and simple testing framework and test it against alternatives.

Keywords: Complementarity; Supermodularity; Firm performance

1. Introduction

Researchers in the fields of industrial organization and management have long been interested in investigating complementary relations between various organizational practices. Complementarity is understood in this context to exist if the implementation of one practice increases the marginal or incremental return to other practices. Joint implementation of several practices may result in economies of scope (Baumol et al., 1988). The implementation of one practice might also decrease the marginal or incremental return to other practices. This is the case of substitutability (or subadditivity). Examples of studies of complementarity are the relationships between human resource practices and firm strategy (Ichniowski et al., 1997), firms' internal R&D and external technology sourcing (Arora and Gambardella, 1994), process and product innovation (Miravete and Pernias, 2004), labor skill and innovation strategies (Leiponen, 2005), different government innovation policies (Mohnen and Röller, 2005), information technology, workplace reorganization, and new product and service innovations (Black and Lynch, 2001; Bresnahan et al, 2002; Caroli and Van Reenen, 2001), adoption of different information technologies in emergency health care (Athey and Stern, 2002), different types of labor in the determination of trade patterns (Grossman and Maggi, 2000) and use of external knowledge across different stages of new product development (Love and Roper, 2009).

There are two econometric approaches used to test for complementarity: the “adoption” or “correlation” approach and the “production function” approach (e.g. Athey and Stern, 1998). The former has been popular among empirical researchers due to its simplicity (Arora, 1996). The adoption approach tests conditional correlations based on the residuals of reduced form regressions of the practices of interest on all exogenous variables. However, although this test can serve as supportive evidence of complementarity, it cannot serve as a definitive test. Estimated correlations between residuals may be the result of common omitted exogenous variables or measurement errors. Even in the case of well-measured correlation between practices, decision makers may not have been sufficiently well informed such that they chose efficiency or output enhancing combinations of practices.

The “production function” approach, in which organizational performance is related to combinations of organizational practices, does not have these drawbacks and can serve as a direct test for complementarity or substitutability.¹ However, no easily executable testing procedure has been available to test for complementarity or substitutability with more than two practices.² Studies adopting the production function approach have limited analysis to the estimation of pair-wise

¹ That is, as long as the population of organizations includes a reasonable number of organizations that take non-optimal combinations of practices. In addition, omitted organizational practices may bias the test procedure.

² Mohnen and Roller (2005) adopt a multiple-inequality restrictions framework but it is limited to dichotomous variables and their testing framework has the disadvantage of an inconclusive area.

interaction effects, either including all pair-wise terms (e.g. Caroli and Van Reenen, 2001), or estimating only the pair-wise interaction of interest (e.g. Bresnahan et al, 2002). This approach ignores the impact of additional cross-terms (e.g. a triple term in case of three practices), it examines only a partial expression for the cross derivative and is prone to an omitted variable bias that affects all coefficients. As noted by Athey and Stern (1998), a proper complementarity or substitutability test requires a testing framework that considers the complete set of organizational practices. In this paper we develop such a test based on a multiple-inequality restrictions framework corresponding to a definition of strict supermodularity or submodularity (Milgrom and Roberts, 1990). We provide Monte Carlo results comparing the power of this test with the performance of the two pair-wise tests.

2. Complementarity and substitutability

We describe the definitions and conditions concerning complementarity and substitutability both for the case of continuously measured practices and the case of dichotomous practices. Consider an objective function f of which the value is determined by the practices x_p ($p=1,\dots,n$). In case the practices are measured continuously the following definition of complementarity holds (e.g. Baumol et al., 1988):³

Definition 1 (continuous practices)

Practices x_i and x_j are considered complementary in the function f if and only if $\partial^2 f / \partial x_i \partial x_j \geq 0$ for all values of (x_1, \dots, x_n) with the inequality holding strictly for at least one value.

This definition is strict in the sense of requiring the cross derivative to be non-negative for all possible or observed values of practices. The definition for substitutability is identical to definition 1 except that ‘larger’ is replaced by ‘smaller’. We use a cross-term specification of the objective function f to test for complementarity or substitutability. The expressions for n equal to 2, 3 and 4 are:

$$f(x_1, x_2) = \alpha_0 + \alpha_1 x_1 + \alpha_2 x_2 + \alpha_{12} x_1 x_2 \quad (1)$$

$$f(x_1, x_2, x_3) = f(x_1, x_2) + \alpha_3 x_3 + \alpha_{13} x_1 x_3 + \alpha_{23} x_2 x_3 + \alpha_{123} x_1 x_2 x_3 \quad (2)$$

$$f(x_1, x_2, x_3, x_4) = f(x_1, x_2, x_3) + \alpha_4 x_4 + \alpha_{14} x_1 x_4 + \alpha_{24} x_2 x_4 + \alpha_{34} x_3 x_4 + \alpha_{134} x_1 x_3 x_4 \\ + \alpha_{124} x_1 x_2 x_4 + \alpha_{234} x_2 x_3 x_4 + \alpha_{1234} x_1 x_2 x_3 x_4 \quad (3)$$

³ In case all bilateral combinations of practices satisfy complementarity, the objective function is strictly supermodular.

The cross-derivatives $\partial^2 f / \partial x_1 \partial x_2$ are equal to α_{12} for equation (1), $\alpha_{12} + \alpha_{123}x_3$ for equation (2) and $\alpha_{12} + \alpha_{123}x_3 + \alpha_{124}x_4 + \alpha_{1234}x_3x_4$ for equation (3), respectively. This implies that there is complementarity for the case of two practices if $\alpha_{12} > 0$. In case of three practices there are two conditions: $\alpha_{12} + \alpha_{123} \min(x_3) \geq 0$ and $\alpha_{12} + \alpha_{123} \max(x_3) \geq 0$ with at least one of the inequalities holding. In case of four practices there are four conditions, using the minimum and maximum of x_3 and x_4 , consecutively. We will concentrate upon the case of three and four practices, although the arguments can easily be extended to higher numbers of multiple practices. Figure 1 shows areas of complementarity and substitutability (or neither) in case of three practices and $x_3 \in [0,1]$. The latter can be seen as an adoption rate of a practice, running from 0% (no adoption) to 100% (complete adoption).⁴ The areas of complementarity and substitutability include the bold lines but not the origin (0,0).

In case the practices take on discrete values variables (step size chosen equal to one) we replace the derivative in definition 1 by a difference. If we consider the first two practices, without loss of generality, the following definition holds:

Definition 2 (discrete practices)

Practices x_1 and x_2 are considered complementary in the function f if and only if $f(x_1 + 1, x_2 + 1, x_3, \dots, x_n) + f(x_1, x_2, x_3, \dots, x_n) \geq f(x_1 + 1, x_2, x_3, \dots, x_n) + f(x_1, x_2 + 1, x_3, \dots, x_n)$ for all values of (x_1, \dots, x_n) with the inequality holding strictly for at least one value.

The case of dichotomously measured practices (practice is used or not) is a special case of this definition. In that case functions (1), (2), and (3) can also be conveniently rewritten in terms of the possible combinations of practices (cf. Mohnen and Röller, 2005). With two practices the collection of possible combinations is defined in the usual binary order as $D = \{ (0,0), (0,1), (1,0), (1,1) \}$. We introduce the indicator function $I_{D=(r,s)}$, equal to one when the combination is (r,s) , else zero. Similar, we have $I_{D=(r,s,t)}$ for the case of three practices. The functions f are rewritten as:

$$f(x_1, x_2) = \sum_{r=0}^1 \sum_{s=0}^1 \beta_{rs} I_{(x_1, x_2)=(r,s)} \quad (4)$$

$$f(x_1, x_2, x_3) = \sum_{r=0}^1 \sum_{s=0}^1 \sum_{t=0}^1 \beta_{rst} I_{(x_1, x_2, x_3)=(r,s,t)} \quad (5)$$

⁴ Practices that are differently scaled may be rescaled to the unit interval [0,1]. For example, a practice x that can take any real value, both positive or negative, can be rescaled as $\exp(x)/(1+\exp(x))$.

The conditions of complementarity now correspond to $\alpha_{12} = f(1,1) - f(1,0) - f(0,1) + f(0,0) = \beta_{11} + \beta_{00} - \beta_{10} - \beta_{01} > 0$ for two practices and $\alpha_{12} = \beta_{110} + \beta_{000} - \beta_{100} - \beta_{010} \geq 0$ and $\alpha_{12} + \alpha_{123} = \beta_{111} + \beta_{001} - \beta_{101} - \beta_{011} \geq 0$ for three practices, with one of the two inequalities holding strictly.

3. The testing procedure

In case of two practices the test for global complementarity is a one-sided t-test of the null hypothesis of $\alpha_{12} = 0$ in equation (1). However, in the general case of n practices, the number of constraints that have to be tested simultaneously is 2^{n-2} . One approach is to apply statistical tests along the lines of Gouriéroux, Holly, and Monfort (1982), Kodde and Palm (1986) and Wolak (1989).⁵ This procedure is followed by Mohnen and Röller (2005) for dichotomously measured practices. The critical values of such tests are however cumbersome to derive. This limits applicability. In addition the test requires software able to do linear regression under inequality constraints. We propose a simpler procedure, which we explain for three and four practices (for five practices, see the Appendix), all measured in the unit interval $[0,1]$: $0 \leq x_3, x_4 \leq 1$. This also includes the case of dichotomously measured practices. Our procedure is a separate induced test, where a combined hypothesis is accepted if all the separate hypotheses are accepted (Savin, 1980). For three practices we have:

$$y = \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3 + \alpha_{12} x_1 x_2 + \alpha_{13} x_1 x_3 + \alpha_{23} x_2 x_3 + \alpha_{123} x_1 x_2 x_3 + \varepsilon \quad (6)$$

where $\varepsilon \sim N(0, \sigma_\varepsilon^2)$. There is complementarity between practices 1 and 2 if $\alpha_{12} \geq 0$ and $\alpha_{12} + \alpha_{123} \geq 0$ with at least one of the two inequalities holding strictly. Now we rewrite equation (6) into:

$$y = \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3 + \alpha_{12} (x_1 x_2 - x_1 x_2 x_3) + \alpha_{13} x_1 x_3 + \alpha_{23} x_2 x_3 + (\alpha_{12} + \alpha_{123}) x_1 x_2 x_3 + \varepsilon \quad (7)$$

The test can now be executed using linear regression and considering the significance of the coefficients of the variables $x_1 x_2 - x_1 x_2 x_3$ and $x_1 x_2 x_3$. Say that the t-value of the former is t_1 and of the latter t_2 , then the new test indicates complementarity if *either* “ $t_1 > t_c$ and $t_2 > -t_d$ ” *or* “ $t_1 > -t_d$ and $t_2 > t_c$ ” where t_c and t_d are the critical t-values depending upon the significance level. The test

⁵ For a Bayesian approach, see Oh (1998).

indicates substitutability if *either* “ $t_1 < -t_c$ and $t_2 < t_d$ ” or “ $t_1 < t_d$ and $t_2 < -t_c$ ”. For four practices we have:

$$y = \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3 + \alpha_4 x_4 + \alpha_{12} x_1 x_2 + \alpha_{13} x_1 x_3 + \alpha_{14} x_1 x_4 + \alpha_{23} x_2 x_3 + \alpha_{24} x_2 x_4 + \alpha_{34} x_3 x_4 + \alpha_{123} x_1 x_2 x_3 + \alpha_{124} x_1 x_2 x_4 + \alpha_{134} x_1 x_3 x_4 + \alpha_{234} x_2 x_3 x_4 + \alpha_{1234} x_1 x_2 x_3 x_4 + \varepsilon \quad (8)$$

This can be rewritten into:

$$y = \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3 + \alpha_4 x_4 + \alpha_{12} (x_1 x_2 + x_1 x_2 x_3 x_4 - x_1 x_2 x_3 - x_1 x_2 x_4) + \alpha_{13} x_1 x_3 + \alpha_{14} x_1 x_4 + \alpha_{23} x_2 x_3 + \alpha_{24} x_2 x_4 + \alpha_{34} x_3 x_4 + (\alpha_{12} + \alpha_{123}) (x_1 x_2 x_3 - x_1 x_2 x_3 x_4) + (\alpha_{12} + \alpha_{124}) (x_1 x_2 x_4 - x_1 x_2 x_3 x_4) + \alpha_{134} x_1 x_3 x_4 + \alpha_{234} x_2 x_3 x_4 + (\alpha_{12} + \alpha_{123} + \alpha_{124} + \alpha_{1234}) x_1 x_2 x_3 x_4 + \varepsilon \quad (9)$$

The test on complementarity is whether $\alpha_{12} \geq 0$ and $\alpha_{12} + \alpha_{123} \geq 0$ and $\alpha_{12} + \alpha_{124} \geq 0$ and $\alpha_{12} + \alpha_{123} + \alpha_{124} + \alpha_{1234} \geq 0$ with at least one of the four inequalities holding strictly. Hence, we use linear regression and consider significance of the coefficients of the four variables $x_1 x_2 + x_1 x_2 x_3 x_4 - x_1 x_2 x_3 - x_1 x_2 x_4$, $x_1 x_2 x_3 - x_1 x_2 x_3 x_4$, $x_1 x_2 x_4 - x_1 x_2 x_3 x_4$ and $x_1 x_2 x_3 x_4$. Denote the t-values of these coefficients as t_1 , t_2 , t_3 and t_4 . The test indicates complementarity in case one of the following four conditions holds: $(t_1 > t_c) \wedge (t_2 > -t_d) \wedge (t_3 > -t_d) \wedge (t_4 > -t_d)$ or $(t_1 > -t_d) \wedge (t_2 > t_c) \wedge (t_3 > -t_d) \wedge (t_4 > -t_d)$ or $(t_1 > -t_d) \wedge (t_2 > -t_d) \wedge (t_3 > t_c) \wedge (t_4 > -t_d)$ or $(t_1 > -t_d) \wedge (t_2 > -t_d) \wedge (t_3 > -t_d) \wedge (t_4 > t_c)$. Testing for substitutability means that we replace the ‘larger than’ signs by ‘smaller than’ signs. The literature on Bonferroni procedures is now relevant for determining the probability of type I error for the significance level of the combined hypothesis. Given a significance level for the combined hypothesis of A and a total of 2^{n-2} constraints, the (original) Bonferroni procedure suggests a significance level for the separate hypotheses of $A/2^{n-2}$, see e.g. Olejnik et al. (1997), p.391.⁶ That is to reduce the overall probability of a type I error.

Our test procedure performs a multiple-restrictions test directly connected to the definition of complementarity and substitutability. We compare the performance of the multiple-restrictions test with two alternative test procedures used in recent empirical work. The “single cross-term” test procedure only incorporates the cross term of two practices in the estimated equation, and infers complementarity from the estimated coefficient of the cross-term (e.g. Bresnahan et al., 2002). The

⁶ There are more sophisticated, modified, Bonferroni procedures, see e.g. Olejnik et al. (1997). These may further improve our test procedure, but go beyond the scope of this note.

“all cross-term” test follows the same procedure but incorporates all pair-wise cross-terms $x_i x_j$ $i \neq j$ in one equation (e.g. Caroli and Van Reenen, 2001). Another recently proposed procedure is the one by Mohnen and Röller (2005). This procedure tests for strict complementarity and substitutability (where all ‘larger than’ and ‘smaller than’ signs are hypothesized to hold) and therefore is not directly comparable. The procedure is also limited to discrete practices (dummy variables) and by using the Kodde and Palm (1986) critical values has a sizeable inconclusive area. Such inconclusive test outcomes become more likely with the increase of the number of inequality constraints. Furthermore, the test is relatively complicated to execute, requiring optimization under inequality constraints, and difficult to extend to higher numbers of practices.

The performance function in the case of three practices is given in equation (6). The single cross term test imposes $\alpha_{13} = \alpha_{23} = \alpha_{123} = 0$ and judges complementarity to exist if $\alpha_{12} > 0$. This is a simple t-test. The multiple cross-term test applies the same criterion but only imposes $\alpha_{123} = 0$. Obviously, the “single cross-term” and “all cross-term” tests suffer from omitted-variable bias. However, since these tests involve restricted estimation, the estimators of α_{12} are likely to have smaller variance (e.g. Judge et al., 1982, chapter 22). In the next section we devise a Monte Carlo experiment to compare the performance of the three test procedures having a trade-off between bias and precision. Since almost all empirical studies of complementarity in the literature examine the impact of using a certain practice or not, we focus our Monte Carlo experiment on the case of dichotomous variables.

4. Monte Carlo Experiments

The data for our experiments are generated for samples of 1,000 and 5,000 observations. These are common sample sizes when investigating complementarities between organizational practices.⁷ We describe the Monte Carlo experimental procedure for three practices. In the first step the coefficients α_1 through α_{123} are randomly and independently drawn from the standard normal distribution and then rounded to whole or half numbers. In the second step, variables z_1, z_2, z_3 are drawn from the multivariate standard normal distribution. Variables x_1, x_2, x_3 are equal to one when $z_1 > 0, z_2 > 0$ and $z_3 > 0$, respectively, else zero. In order to mimic empirical research settings, the correlation structure between the practices is allowed to depend on the presence of complementarity or substitutability. Organizations are more likely to simultaneously adopt two practices if these are complementary. In case the draws of α_1 through α_{123} indicate complementarity, the correlation coefficient between x_1 and x_2 is set at 0.5 and in case of substitutability at -0.5. The correlation coefficient is set at zero if the

⁷ Examples include Black and Lynch (2001) with a number of observations of about 1,000, Galia and Legros (2004) with about 1,800, Laursen and Foss with about 1,900, Belderbos et al. (2006) with about 2,000, Bresnahan et al. (2002) with about 2,200, Catozzella and Vivarelli (2007) with about 3,000, Mohnen and Röller (2005) with about 5,500 and Cozzarin and Percival (2007) with about 5,900 observations.

draw indicates no complementarity or substitutability.⁸ Equation (6) is used to generate data for y . For four practices a similar procedure and equation (8) are used.

The outcomes of the tests are established using 10% two-sided significance levels. This means that the critical level is equal to 1.65 for the pair-wise tests. We also use $t_d = 1.65$ but t_c equal to 1.96 for the multiple-restriction test when there are three practices and 2.24 when there are four practices. The latter follow from the $A/2^{n-2}$ formula with A equal to 10% and n equal to 3 and 4, respectively. The pair-wise tests consider the sign and t-statistic for $\hat{\alpha}_{12}$. The above procedure has been repeated 10,000 times for models with different explanatory power. Tables 1 through 4 presents the results of the Monte Carlo experiments for models with three different values of σ_ε . These are σ_ε equal to 0.25, 1 and 3.5. These correspond to values for R-squared of approximately 90%, 50% and 10% in case of three practices (Tables 1 and 2). The explanatory power is higher in the case of four practices with R-squared around 95%, 67% and 18%, respectively (Tables 3 and 4). In Tables 1 and 3 we consider 1,000 observations and in Tables 2 and 4 we consider 5,000 observations. In each of the experiments we compare the results of the tests with the true states of complementarity and substitutability.

Our multiple-restrictions test outperforms both the “single cross-term” and “all cross-term” tests in the large majority of cases. Only in case of a model with a low fit (σ_ε equal to 3.5) and a relatively low number of observations vis-à-vis the number of practices, the pair-wise tests appear to perform better. The pair-wise tests perform especially poor in case of four practices. Obviously, in that case there are three further conditions than only $\alpha_{12} > 0$. The pair-wise tests perform relatively poorly in the high explanatory power models (σ_ε equal to 0.25, or 1). Clearly, the problem of bias is more important than the lower variance of $\hat{\alpha}_{12}$ in those cases. The pair-wise tests perform much better in relative terms for the models with low R^2 . The “single cross-term” test shows the highest percentage of correct predictions with for example 63.5% in Table 1 and 71.0% in Table 3. Hence, the simpler tests restricting some of the parameters to zero, benefit from having low variance although at the expense of some bias. We conclude that our multiple-restrictions test is a clearly improved testing framework for complementarity or substitutability but only for models in which practices have a noticeable impact on performance. Otherwise, for three practices, pair-wise tests appear as easily executed alternatives with relatively good predictive power.

5. Conclusion

⁸ For comparison, we executed similar Monte Carlo simulations with correlation coefficients set at 0.8, -0.8 and 0, respectively and without systematic correlation between the practices. We found only limited changes in the comparative accuracy of the tests. Obviously, tests of complementarity and substitutability perform better when there is lack of multicollinearity among practices.

Recent empirical studies of organizational performance have been concerned with establishing potential complementarity between more than two organizational practices adopted simultaneously. These papers have drawn conclusions on the basis of potentially biased estimates of pair-wise interaction effects between such practices. This paper developed a consistent and simple testing framework based on multiple inequality constraints that derives from the definition of (strict) supermodularity as suggested by Athey and Stern (1998), and compares the performance of this test with previously used methods. Monte Carlo results show that this multiple-restrictions test is generally superior for performance models.

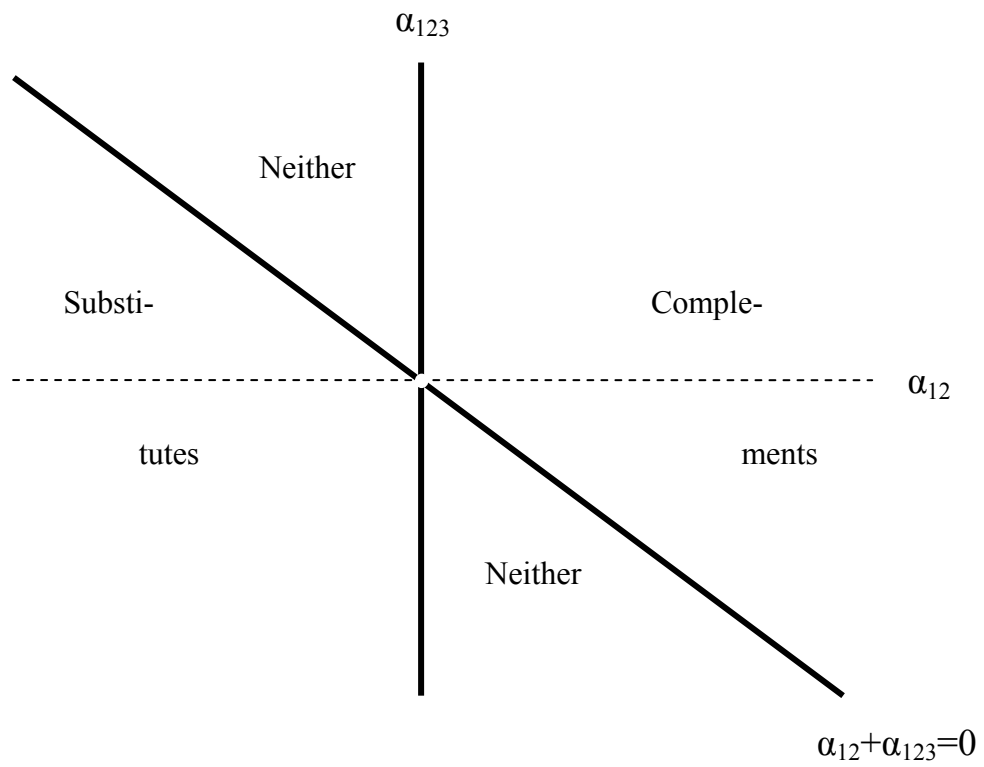

Figure 1: Areas of complementarity and substitutability

Appendix: General overview of variables and hypotheses

The following table provides the relevant variables in the regression equation and the related hypotheses, for up to five practices, to allow for easy extension.

Table A1 Variables and hypotheses

n	variable	hypothesis
3	$x_1x_2x_3$	$\alpha_{12} + \alpha_{123} \geq 0$
	$x_1x_2(1-x_3)$	$\alpha_{12} \geq 0$
4	$x_1x_2x_3x_4$	$\alpha_{12} + \alpha_{123} + \alpha_{124} + \alpha_{1234} \geq 0$
	$x_1x_2x_3(1-x_4)$	$\alpha_{12} + \alpha_{123} \geq 0$
	$x_1x_2(1-x_3)x_4$	$\alpha_{12} + \alpha_{124} \geq 0$
	$x_1x_2(1-x_3)(1-x_4)$	$\alpha_{12} \geq 0$
5	$x_1x_2x_3x_4x_5$	$\alpha_{12} + \alpha_{123} + \alpha_{124} + \alpha_{125} + \alpha_{1234} + \alpha_{1235} + \alpha_{1245} + \alpha_{12345} \geq 0$
	$x_1x_2x_3x_4(1-x_5)$	$\alpha_{12} + \alpha_{123} + \alpha_{124} + \alpha_{1234} \geq 0$
	$x_1x_2x_3(1-x_4)x_5$	$\alpha_{12} + \alpha_{123} + \alpha_{125} + \alpha_{1235} \geq 0$
	$x_1x_2(1-x_3)x_4x_5$	$\alpha_{12} + \alpha_{124} + \alpha_{125} + \alpha_{1245} \geq 0$
	$x_1x_2x_3(1-x_4)(1-x_5)$	$\alpha_{12} + \alpha_{123} \geq 0$
	$x_1x_2(1-x_3)x_4(1-x_5)$	$\alpha_{12} + \alpha_{124} \geq 0$
	$x_1x_2(1-x_3)(1-x_4)x_5$	$\alpha_{12} + \alpha_{125} \geq 0$
	$x_1x_2(1-x_3)(1-x_4)(1-x_5)$	$\alpha_{12} \geq 0$

The UNU-MERIT WORKING Paper Series

- 2010-01 *Endogenous Economic Growth through Connectivity* by Adriaan van Zon and Evans Mupela
- 2010-02 *Human resource management and learning for innovation: pharmaceuticals in Mexico* by Fernando Santiago
- 2010-03 *Understanding multilevel interactions in economic development* by Micheline Goedhuys and Martin Srholec
- 2010-04 *The Impact of the Credit Crisis on Poor Developing Countries and the Role of China in Pulling and Crowding Us Out* by Thomas H.W. Ziesemer
- 2010-05 *Is there complementarity or substitutability between internal and external R&D strategies?* by John Hagedoorn and Ning Wang
- 2010-06 *Measuring the Returns to R&D* by Bronwyn H. Hall, Jacques Mairesse and Pierre Mohnen
- 2010-07 *Importance of Technological Innovation for SME Growth: Evidence from India* by M. H. Bala Subrahmanya, M. Mathirajan and K. N. Krishnaswamy
- 2010-08 *Economic Adversity and Entrepreneurship-led Growth: Lessons from the Indian Software Sector* by Suma Athreya
- 2010-09 *Net-immigration of developing countries: The role of economic determinants, disasters, conflicts, and political instability* by Thomas H.W. Ziesemer
- 2010-10 *Business and financial method patents, innovation, and policy* by Bronwyn H. Hall
- 2010-11 *Financial patenting in Europe* by Bronwyn H. Hall, Grid Thoma and Salvatore Torrisi
- 2010-12 *The financing of R&D and innovation* by Bronwyn H. Hall and Josh Lerner
- 2010-13 *Occupation choice: Family, Social and Market influences* by Ezequiel Tacsir
- 2010-14 *Choosing a career in Science and Technology* by Ezequiel Tacsir
- 2010-15 *How novel is social capital: Three cases from the British history that reflect social capital* by Semih Akcomak and Paul Stoneman
- 2010-16 *Global Players from Brazil: drivers and challenges in the internationalization process of Brazilian firms* by Flavia Carvalho, Ionara Costa and Geert Duysters
- 2010-17 *Drivers of Brazilian foreign investments – technology seeking and technology exploiting as determinants of emerging FDI* by Flavia Carvalho, Geert Duysters and Ionara Costa
- 2010-18 *On the Delivery of Pro-Poor Innovations: Managerial Lessons from Sanitation Activists in India* by Shyama V. Ramani, Shuan SadreGhazi and Geert Duysters
- 2010-19 *Catching up in pharmaceuticals: a comparative study of India and Brazil* by Samira Guennif and Shyama V. Ramani
- 2010-20 *Below the Radar: What does Innovation in Emerging Economies have to offer other Low Income Economies?* by Raphael Kaplinsky, Joanna Chataway, Norman Clark, Rebecca Hanlin, Dinar Kale, Lois Muraguri, Theo Papaioannou, Peter Robbins and Watu Wamae
- 2010-21 *Much ado about nothing, or sirens of a brave new world? MNE activity from developing countries and its significance for development* by Rajneesh Narula
- 2010-22 *From trends in commodities and manufactures to country terms of trade* by Thomas H.W. Ziesemer
- 2010-23 *Using innovation surveys for econometric analysis* by Jacques Mairesse and Pierre Mohnen

- 2010-24 *Towards a New Measurement of Energy Poverty: A Cross-Community Analysis of Rural Pakistan* by Bilal Mirza and Adam Szirmai
- 2010-25 *Discovery of the flower industry in Ethiopia: experimentation and coordination* by Mulu Gebreeyesus and Michiko Iizuka
- 2010-26 *CSR and market changing product innovations: Indian case studies* by Shyama V. Ramani and Vivekananda Mukherjee
- 2010-27 *How firms innovate: R&D, non-R&D, and technology adoption* by Can Huang, Anthony Arundel and Hugo Hollanders
- 2010-28 *Sure Bet or Scientometric Mirage? An Assessment of Chinese Progress in Nanotechnology* by Can Huang and Yilin Wu
- 2010-29 *Convergence of European regions: a reappraisal* by Théophile T. Azomahou, Jalal Elouardighi, Phu Nguyen-Van and Thi Kim Cuong Pham
- 2010-30 *Entrepreneurship and the National System of Innovation: What is Missing in Turkey?* by Elif Bascavusoglu-Moreau
- 2010-31 *Keeping the eclectic paradigm simple: a brief commentary and implications for ownership advantages* by Rajneesh Narula
- 2010-32 *Brazilian Aerospace Manufacturing in Comparative Perspective: A Brazil/USA Comparison of Output and Productivity* by Daniel Vertesy and Adam Szirmai
- 2010-33 *Economic restructuring and total factor productivity growth: Tunisia over the period 1983-2001* by Sofiane Ghali and Pierre Mohnen
- 2010-34 *Impact of government support on R&D and innovation* by Abraham Garcia and Pierre Mohnen
- 2010-35 *Product, process and organizational innovation: drivers, complementarity and productivity effects* by Michael Polder, George van Leeuwen, Pierre Mohnen and Wladimir Raymond
- 2010-36 *Entrepreneurship Development and the Role of Economic Transition in Entrepreneurial Activities in China* by Ying Zhang and Geert Duysters
- 2010-37 *Pro-Poor, Entrepreneur-Based Innovation and its Role in Rural Development* by Lina Sonne
- 2010-38 *Financing pro-poor entrepreneur-based innovation: A review of existing literature* by Lina Sonne
- 2010-39 *India's Rural Financial System: Does it Support Pro-Poor Innovation?* by Lina Sonne
- 2010-40 *How effective are level-based R&D tax credits? Evidence from the Netherlands* by Boris Lokshin and Pierre Mohnen
- 2010-41 *Analysing Multidimensional Poverty in Guinea: A Fuzzy Set Approach* by Fatoumata Lamarana Diallo
- 2010-42 *Bottom-up, Bottom-line: Development-Relevant Enterprises in East Africa and their Significance for Agricultural Innovation* by Andy Hall, Norman Clark and Andy Frost
- 2010-43 *Assessing Innovations in International Research and Development Practice* by Laxmi Prasad Pant
- 2010-44 *Research Into Use: Investigating the Relationship between Agricultural Research and Innovation* by Andy Hall, Jeroen Dijkman and Rasheed Sulaiman V.
- 2010-45 *The global institutional frameworks and the diffusion of renewable energy technologies in the BRICS countries* by Isabel Maria Freitas, Eva Dantas & Michiko Iizuka
- 2010-46 *The role of patent protection in (clean/green) technology transfer* by Bronwyn H. Hall and Christian Helmers

- 2010-47 *Localisation Strategies of Firms in Wind Energy Technology Development* by Radhika Perrot and Sergey Filippov
- 2010-48 *The R&D activity of multinational enterprises in peripheral economies: evidence from the EU new member states* by Rajneesh Narula and José Guimón
- 2010-49 *Bridging the Financing Gap for Pro-Poor Innovation: Towards a Framework* by Lina Sonne
- 2010-50 *Efficient Development Portfolio Design for Sub Saharan Africa* by Adriaan van Zon and Kirsten Wiebe
- 2010-51 *Global excellence at the expense of local relevance, or a bridge between two worlds? Research in science and technology in the developing world* by Helena Barnard, Robin Cowan, Moritz Müller
- 2010-52 *Innovation strategy, firm survival and relocation: The case of Hong Kong-owned manufacturing in Guangdong province, China* by Naubahar Sharif and Can Huang
- 2010-53 *Determinants of PRO-industry interactions in pharmaceutical R&D: the case of Mexico* by Fernando Santiago Rodriguez and Gabriela Dutrenit
- 2010-54 *New Organisational and institutional vehicles for managing innovation in South Asia: Opportunities for using research for technical change and social gain* by Vamsidhar Reddy, T.S., Andy Hall and Rasheed Sulaiman V.
- 2010-55 *Public R&D subsidies and productivity: Evidence from firm-level data in Quebec* by Rufin Baghana
- 2010-56 *A note on testing for complementarity and substitutability in the case of multiple practices* by Martin Carree, Boris Lokshin and René Belderbos
