Online travel service quality: The importance of pre-transaction services

ABSTRACT *The Internet revolution has led to significant changes in the way travel agencies interact with customers. Travel websites are used to different degrees, and for a variety of combinations of pre-transaction, transaction and post-transaction services. A better understanding of how customers interact with online services will help providers improve service quality to levels that satisfy or even delight customers, and thus create loyalty. This article provides a comprehensive review of the literature on online service quality, applies the theory to online travel offerings, and reports on an empirical study of quality perceptions of pre-transaction services provided on three travel websites. Effects on customer perceived quality were measured for process and outcome dimensions of online services. Implications for the design of online travel services and suggestions for further research are formulated.*

Introduction

Travel agencies provide services that largely consist of information exchange and information processing activities. Promotional information and information that should support the customer in their travel decision-making is generally provided in pre-transaction services. In transaction services the customers' personal information and payments are collected, verified and processed, and information is relayed to third party transportation and hospitality providers. Finally, in post-transaction services travel agents communicate last-minute information to the customer and provide after-sales assistance. As the travel industry is largely information-driven, the World Wide Web is considered ideally suited as a medium for these activities (Adamic & Huberman, 2000; Morgan *et al.*, 2001; Peterson *et al.*, 1997), and it is hardly surprising that Online travel services have developed into one of the largest e-commerce domains (Anckar & Walden, 2000; Clemons *et al.*, 2002). There is great diversity among travel agencies' use of IT and the Web. Most traditional travel agencies have at least a basic presence on the Internet to promote their business or to exchange e-mail with customers. More sophisticated travel sites allow customers to search, select or arrange travel and holiday packages, and make reservations and bookings themselves. In spite of the slowdown occurring in other e-commerce areas, the online travel business has shown sustained growth (TravelWeekly, 2001).

The Internet has increased competition among travel agents considerably. Even if price plays only a secondary role in online services (Pan *et al.*, 2002; Reichheld & Schefter, 2000; Smith, 2002), the information efficiency of the Internet still poses a substantial threat, as all online travel agencies offer similar services. Service quality can create differentiation between providers, thereby easing price competition (Clemons *et al.*, 2002), and may therefore be among the most important success factors of any Internet business (Zeithaml *et al.*, 2002). Excellent online service will satisfy or even delight customers and increase their patronage (Rust & Oliver, 2000), resulting in desirable behaviors such as word-of-mouth promotion, willingness to pay a price premium and repurchasing (Reichheld *et al.*, 2000; Reichheld & Schefter, 2000; Reichheld & Teal, 1996). Nonetheless, few sites are reported to appeal to their customers, and even fewer create significant value (Grönroos *et al.*, 2000).

The issue of quality management has become quintessential in the travel and tourism industry, which is suffering from a general slowdown since September 11, the wars in Afghanistan and Iraq, and the outbreak of the SARS virus in Asia. The increased importance of quality, satisfaction and loyalty in the tourism and travel business (Augustyn, 1998; Augustyn

& Ho, 1998), and the role of the Internet in this encounter, has led to surprisingly few research articles dedicated to the management of online (self-) service encounter quality in the travel domain. Research in the field of customer evaluations of self-service technology (Dabholkar, 1996; Meuter *et al.*, 2000) and online services is generally considered in an early stage. Developing general insight in the determinants of perceived e-service quality and the influence of e-service quality on satisfaction and loyalty is of great interest, but in itself insufficient, since the dimensionality of service quality is considered dependent on the type of services offered (Babakus & Boller, 1992). This observation increases the need for research focusing on specific services. For travel agencies desiring to survive and thrive on the Internet, and thus willing to invest in online services, it is critical to know precisely how customers will evaluate their services and which quality dimensions are valued most (Jeong & Lambert, 2001; Jeong *et al.*, 2003). Hence, the problem statement of the present study reads:

Which factors play a role in customer evaluations of online travel service quality?

Three sub-questions were formulated:

- (1) How do customers perceive and use online travel services?
- (2) To what extent can traditional measures be used for online service quality?
- (3) Which quality dimensions do customers of online travel services consider important?

The study aims to explore the issue of customer quality perceptions of travel websites. First, differences in the way consumers perceive and use traditional and online services will be identified, and the consequences of these differences for the conceptualization of online travel service quality will be discussed. A model of online travel service quality will be developed, which will be validated in an empirical study. In the conclusion, implications and directions for future research are presented.

Review of the literature and development of propositions

Loyal customers are important to companies, because they contribute directly to the profitability and viability of the firm. Online customers express their loyalty to a service provider in various ways (Reichheld, 1994; Reichheld *et al.*, 2000; Reichheld & Teal, 1996; Viitanen *et al.*, 2003; Zeithaml *et al.*, 1996). It is reflected in return- and repurchase behavior and favorable word-of-mouth. In an online setting, word-of-mouth can spread quickly. On-line customers can use e-

mail, often offered in the form of a link, to recommend their favorite web site to friends and family.

Positive and reciprocal relationships are often assumed to exist between customer loyalty, service quality, and customer satisfaction in offline and online contexts (Bowen & Clarke, 2002; Shankar *et al.*, 2003), although the precise nature of these relationships, and the validity of offline loyalty theories in an online environment are still under debate (Jeong *et al.*, 2003). Indeed, loyal customers are typically satisfied customers, but satisfaction does not universally translate into loyalty (Oliver, 1999). Service quality and customer satisfaction have been used interchangeably as antecedents of loyalty, but a feeling of consensus is growing that they are fundamentally different in terms of antecedents and outcomes (Zeithaml & Bitner, 2000). Causal links are thought to exist between service quality, satisfaction and loyalty, while nature, direction and strength of the links depend on the type of service (Dabholkar, 1996) and the position in the customer-provider relationship lifecycle. Transaction and post-transaction service quality is considered crucial to overall loyalty (Reibstein, 2002), while in the case of online travel services, satisfaction with pre-transaction services will be important, as it leads to return and favorable word-of-mouth behavior. Positive service quality perceptions are assumed to lead to increased satisfaction, “*the perception of pleasurable fulfillment*” (Oliver, 1999: p. 34) and value attributions (Zeithaml & Bitner, 2000). Conversely, Dabholkar (1996) found that satisfaction with the use of technology has a substantial effect on service quality evaluations. It appears very difficult, if not impossible, to influence satisfaction, loyalty or patronizing behavior of customers directly. However, service quality can more easily be assessed, managed and controlled. In the following we will therefore focus on online service quality.

A conceptualization of online travel services

In analogy with other services, online travel services can be viewed as a composite offer, consisting of core services and peripheral or auxiliary services (Grönroos, 1994; Grönroos *et al.*, 2000). In a traditional service context, the reason for the provider to be on the market is generally seen as the core service (e.g. selling travel packages for a traditional travel agent), while the auxiliary services are considered to exist in order to facilitate the use of the core service or to enhance the value of the offer. The situation is considerably different in an online context. Whereas it may be obvious to customers of traditional providers what their core services are, this is not the case in an online environment. What customers perceive as the core service will depend on their momentary needs and preferences regarding the Web. To leisure

customers, who may prefer making actual transactions in the travel agency, pre-transaction services could comprise the core service of a travel website, while transaction services may constitute the core service for business customers. Building on Grönroos' (1994) theory, and mindful of the idea of 'customerization' (Wind & Rangaswamy, 2001), we propose an adapted – genuinely customer-based - conceptualization of online services: The online core service will be the customer's reason for using the website, whether this service is making a transaction, or making use of pre- or post-transaction services.

This adaptation has consequences for the conceptualization of online auxiliary services. Auxiliary services have been subdivided into facilitating and supporting services. Facilitating services are considered essential for making the service accessible (Grönroos *et al.*, 2000). In the case of an online travel agency, facilitating services would for example consist of search engines, reservation systems and secure paying methods. Although facilitating services are essential – and thus common to all competing service offers – they can still be designed in a distinctive fashion, adding value for the customer (Grönroos *et al.*, 2000).

Supporting services tend to be considered non-essential, added to the website mainly to differentiate the service package (Grönroos *et al.*, 2000). For online travel agencies, supporting services would be currency calculators, weather forecasts, information about health issues, general country information, chat-rooms, traveler storybooks, or links to other websites. As explained in the above, it is conceivable, that customers view certain supporting services as the core service or as an indiscernible part of the core service. For instance when the customer uses a travel agent's website uniquely for checking the local weather forecast, typically a pre- or post transaction service. In an online context, the role of supporting services must therefore be reconsidered: While they may not seem essential to the provider, supporting services are often essential to the customer, and therefore potentially very important in distinguishing the service offer from those of competitors.

Modeling and measuring service quality

In a traditional service setting, customers are often thought to base their quality judgments mainly on evaluations of the physical aspects of the service provider on the one hand (Bitner, 1992), and their interactions with service employees on the other (Bitner, 1990; Bitner *et al.*, 1990). In service quality research, the so-called service encounter (Solomon *et al.*, 1985) is often identified with the service itself (Groth, 2001). Especially the quality and perceived value of human interaction between customer and service staff during the encounter (Bolton & Drew,

1992) are considered critical in determining future patronage behavior. Parasuraman *et al.* (1985; 1988) were the first to introduce a formal service quality model. The model was based on the disconfirmation paradigm, introduced to consumer behavior research by Oliver (1977). A combination of theoretical and empirical research resulted in the 22-item SERVQUAL scale (Parasuraman *et al.*, 1985; Parasuraman *et al.*, 1988), that has since become widely accepted and used: Service quality is measured along five fundamental quality dimensions: *tangibles* (appearance of physical facilities, equipment, personnel, and communication materials), *reliability* (the ability of the firm to perform the promised service dependably and accurately), *responsiveness* (willingness to help customers and provide prompt service), *assurance* (knowledge and courtesy of employees and their ability to convey trust and confidence), and *empathy* (the caring and individualized attention provided to the customer).

At the same time, the dimensionality of the SERVQUAL model has been brought into question (Brown *et al.*, 2002; Caruana, 2000). The five-component factor structure is indeed confirmed in few if any of the research samples (Caruana, 2000; Cronin Jr. & Taylor, 1992). This lack of confirmation has been explained by suggesting that the dimensionality is dependent on the type of service being offered (Babakus & Boller, 1992). To what extent the SERVQUAL-model can be used for online services is also under debate. Several authors have proposed the use of traditional service quality theory as a basis for further empirical research (Grönroos *et al.*, 2000; Kaynama & Black, 2000; Zeithaml *et al.*, 2000). Zeithaml *et al.* (2000) for example developed 11 SERVQUAL-related dimensions based on focus group research. According to Liljander *et al.* (2002) the original dimensions can be adapted, and some additional dimensions should be constructed. The conceptualization of online services as a Self Service Technology (SST), enabling customers to service themselves without the involvement of employees, can be helpful in adapting the original SERVQUAL dimensions (Dabholkar, 1996; Dabholkar, 2000; Dabholkar & Bagozzi, 2002; Meuter & Bitner, 1998; Meuter *et al.*, 2001; Meuter *et al.*, 2000). In many online service encounters, customers exclusively interact with technology and will only deal with employees when special help is needed. Furthermore, a visit to the provider's premises is no longer necessary. The traditional service encounter is thus replaced by an interaction with technology and it can be expected that online service quality perceptions will be based on evaluations of this interaction. A key determinant of online service quality appears to be the user interface (Grönroos *et al.*, 2000).

The user interface

Technology can enable and facilitate the exchange of information between customers and the service provider (Parasuraman & Grewal, 2000). In the case of online services, information technology is observable in the user interface (Grönroos *et al.*, 2000). Therefore, an important quality dimension customers encounter when visiting a website is its functionality as an interface between themselves and the firm. Making a distinction between the *process* or technical and *outcome* or functional aspects of service quality (Grönroos, 1994; Grönroos *et al.*, 2000; Parasuraman *et al.*, 1985; Parasuraman *et al.*, 1991) the role of the user interface and the relationships between the various components of the online service offer and customer responses can be visualized as depicted in Figure 1.

Please take in Figure 1

The technical functionality of the user interface determines *how* services are delivered to customers, and affects quality perceptions of the core, facilitating and supporting services (Liljander *et al.*, 2002). Since the user interface substitutes for the physical service encounter, it also reflects the *tangibles* dimension of the SERVQUAL model (Kaynama & Black, 2000; Szymanski & Hise, 2000). The extent to which the website succeeds as an interface between customer and provider will likely depend on two broad characteristics: the design of the pages as they appear on screen, and the ease with which customers can navigate between pages inside the website. The structure of travel websites is highly complicated, because they must allow the customer to retrieve and select detailed information chunks from many different databases and combine them into the desired information (Barnett & Standing, 2001). The complexity of the travel offer also makes it difficult to display all required information efficiently and effectively. It is therefore expected, that the quality of the user interface will play a major role in the case of Internet travel agencies (Jeong *et al.*, 2003). Propositions will now be formulated with respect to the role and importance of each of the dimensions for the case of online travel agencies. Zeithaml *et al.* (2000) suggest measuring user interface quality in three dimensions, namely accessibility, navigation and aesthetics. We follow this approach in formulating three propositions relating to the user interface, which precede propositions with respect to the other four modified SERVQUAL dimensions.

Accessibility

High levels of interface quality would imply easy access to the site itself, to company staff, and to the different services when needed (Bell & Tang, 1998; Cox & Dale, 2001; Zeithaml *et al.*, 2000). Therefore we propose:

P1: In the case of Internet travel agencies, accessibility of the website, the services and staff will be positively related to overall quality perceptions.

Navigation

Navigation quality implies that the site contains functions helping customers find what they need without difficulty, utilizes a good search engine, and allows the customer to maneuver easily, logically and quickly back and forth through the pages (Jeong & Lambert, 2001; Liljander *et al.*, 2002; Zeithaml *et al.*, 2000). Customers could be offered different ways of searching. For travel sites, high quality navigation would mean that the customers could perform complex searches on e.g. type of transportation, country, date and price. We therefore expect:

P2: In the case of Internet travel agencies, perceived quality of navigation between pages will be positively related to overall quality perceptions.

Design

Design quality is referred to as ‘site aesthetics’ by Zeithaml *et al.* (2000), or e-scape (Van Riel *et al.*, 2004; Viitanen *et al.*, 2003). The way information is presented, in terms of color use, layout, number, relevance and quality of pictures, font size and style will affect the way customers respond to the service. It is thus expected that:

P3: In the case of Internet travel agencies, perceived quality of the design of web pages and the presentation of information will be positively related to overall quality perceptions.

Reliability

Having covered the *tangibles* dimension of SERVQUAL in the *design* aspect of the user interface, the next dimension to be discussed and modified for online services is *reliability*. Similar to the case of offline services, customers expect search engines, payment facilities etc.

to function reliably, and the information presented on the website to be dependable. Two aspects of website reliability can be distinguished (Cox & Dale, 2001) (Cox and Dale, 2001). The process aspect of reliability perceptions is driven by the correct technical functioning of the site, or the technical aspects of the *user interface*, while the outcome aspect is defined by the accuracy of service promises, billing and product information (Zeithaml *et al.*, 2000). For instance, online travel agencies are required to reserve and offer the correct number of seats in an airplane, offer the packages at the advertised prices, and reserve the correct type of hotel room for the number of nights requested by the customer. It can therefore be expected, that:

P4: In the case of Internet travel agencies, perceived reliability of the online services will be positively related to overall quality perceptions.

Assurance

In the SERVQUAL model an important dimension is assurance, or the degree to which the service staff and facilities instigate trust in the customer. Online customers generally cannot scrutinize the employees, or the physical facilities of the firm they are dealing with (Reichheld & Scheffer, 2000), so trust must be established in other ways. The *security and privacy*-dimension used by Zeithaml *et al.* (2000), which "*involves the degree to which the customer believes the site is safe from intrusion and personal information is protected*" (Zeithaml *et al.*, 2000: p. 16) will be included in the assurance dimension. Trust is often claimed to be the most important online service quality dimension (Papadopoulou *et al.*, 2001; Petersen, 2001; Roy *et al.*, 2001; Urban *et al.*, 2000). It is expected, that:

P5: In the case of Internet travel agencies, perceived assurance of the online services will be positively related to overall quality perceptions.

Responsiveness

The quality of support customers receive when faced with questions or running into problems, and the speed with which this support is provided, largely determine customer evaluation of after sales support. Customer support is also appreciated during the pre-transaction stage, particularly for online services: The online customer is relatively powerless in enforcing help, having to rely on the willingness of the firm to provide support. The faster and more accurately a provider responds to requests, the better the service will be evaluated. We therefore expect:

P6: In the case of Internet travel agencies, a positive relationship will exist between perceived responsiveness and overall quality perceptions.

Customization

It has been argued that the ability to customize is one of the key benefits of applying technology to the delivery process of services. As a result, customers expect online services to respond to their individual needs (Bitner *et al.*, 2000). Customization is strongly related to the *empathy* dimension in SERVQUAL, as the online firm shows its appreciation of the customer's unique needs and preferences by making the site adaptable. Companies can also track customers' movements and decisions through interactions with the visited web sites and then use this database of client data for customization (Kaynama & Black, 2000). Customization can easily involve privacy issues: To what extent customers will tolerate prying behavior of online providers remains to be seen. It can be expected, that:

P7: In the case of Internet travel agencies, a positive relationship will exist between perceived customization and overall quality perceptions.

The expected relationships are summarized in the model in Figure 2.

Please take in Figure 2

Research design and methodology

A comparison of three existing travel sites in The Netherlands serves to validate the model by testing the propositions that were developed. After a short description of the travel industry in The Netherlands and of the three travel firms studied, the research methodology and the operationalization of the variables will be discussed.

The travel industry in The Netherlands

The Netherlands is a small country with 15 million inhabitants. It has one of the highest levels of Personal Computer and Internet penetration (Forrester, 2001) in households (after the US and Finland). The travel market can be divided into online, hybrid and traditional agencies. Furthermore, a distinction can be made between direct sellers and intermediaries. *Direct sellers* exclusively offer their own products. Examples are De Jong Intra (www.dejongintra.com), KrasSterVakanties (www.kras.nl), and ATPonline (www.atponline.nl) online. Direct sellers

have direct insight in the availability of products, and can rapidly adapt the products to current demand. A disadvantage is the limited product offering (Jungle, 2001). For this reason, direct sellers tend to transform themselves into intermediaries (Barnett & Standing, 2001). *Intermediaries* provide sites that sell products from a range of tour-operators. E-Bookers (www.ebookers.com), Elmar-reizen (www.elmar.nl), Travelplanet (www.travelplanet.nl), Happytravel (www.happytravel.nl), D-reizen (www.d-reizen.nl) and Travel24 (www.travel24.com) are examples of this category. Intermediaries tend to have the most attractive website design: "When booking through an intermediary you really land in a virtual travel-world, where you can feel, compare and easily book, while a site of a direct seller is often without fantasy and atmosphere" (Jungle, 2001).

Three travel websites

Three travel agencies, representing different categories, were used for this study: D-reizen (hybrid intermediary), Travel24 (online intermediary), and De Jong Intra (hybrid direct seller):

- (1) *D-reizen* is the largest independent travel agency in the Netherlands. They sell bookings for nearly all Dutch tour operators (55 tour-operators, among others De Jong Intra) and airline companies.
- (2) *Travel24* is one of the most prominent travel agencies on the Internet. Travel24 is active in the Dutch-speaking Benelux-market, but also in Germany and other European countries and has agreements with many international tour-operators. Most offerings can be booked online.
- (3) *De Jong Intra* is a tour operator that caters to over 250.000 leisure travelers on a yearly basis. De Jong Intra sells their vacations via their website and through intermediaries (such as D-reizen).

Questionnaire design and measurement

A structured undisguised questionnaire was developed containing 37 closed questions and 5 open questions. The questionnaire was sent by e-mail to a convenience sample of about 400 contacts on May 7th 2002, with the invitation to complete the questionnaire for at least one travel website. 91 respondents completed the questionnaire, 44 respondents for D-reizen, 20 respondents for De Jong Intra, and 27 respondents for Travel24.

In the original SERVQUAL model, service quality is defined as the difference between

customers' expectations or anticipations and their perceptions of actual performance (Parasuraman, 1991). It has been suggested that service quality can be measured more appropriately as performance (Cronin Jr. & Taylor, 1992; Cronin Jr. & Taylor, 1994). Service quality, measured as perceived performance, has been demonstrated to affect customer satisfaction and patronage behavior directly and to a high degree (Cronin Jr. *et al.*, 2000; Liljander & Strandvik, 1995). It was therefore decided to measure service quality by letting respondents express their agreement or disagreement with statements about the performance of the service on the previously discussed dimensions. Performance perceptions were measured on seven point Likert-scales.

Results

In a separate part of the survey, respondents were asked about the importance of various services offered by travel websites in general. Table 1 shows the means and standard deviations of the responses by age group.

Please take in Table 1

Transaction-related services show an importance rating of at least 6 out of 7 in all categories and age groups. A notable difference was observed for *responsiveness*. Online customers in age group 20 – 24 years old appear more impatient than the people in the other age groups. The various facilitating and supporting services show much lower ratings, except for direct access, which reflects the desire to access the provider by phone or visit the premises if needed.

Factor analysis was used to assess the one-dimensional nature of the different variables. Cronbach's alpha was calculated for all constructs to obtain an indication of the reliability of the measures. Three separate factor analyses were conducted, one on the customer responses, one on the three user interface dimensions, and one on the other service quality dimensions. Scree tests were used to determine the number of factors. A value of 1 for the initial Eigenvalues was used as a threshold. The factor loadings for most individual questions, relating to the user interface and the other service quality dimensions were high, whereas the factor analyses yielded relatively high values on the Kaiser–Meyer–Olkin measure of sampling adequacy (see Table 2), so these constructs can be considered reliable and one dimensional. Items measuring overall quality, satisfaction and behavioral intentions loaded on one factor, explaining 65 % of

the total variance.

Please take in Table 2

Means and standard deviations for service quality dimensions and overall rating of each site are reported in Table 3. For De Jong Intra, these values are consistently lower than for the other two sites (except site design).

Please take in Table 3

To further explore the data, we calculated correlations between all main constructs. Table 4 presents the correlations between core constructs. Correlation coefficients of respectively 0.10, 0.30 and 0.50 are typically interpreted as small, medium and large (Green *et al.*, 1997).

Please take in Table 4

Regression analysis was used to test the propositions. The expected relationships between the 7 online service quality dimensions and customer responses are represented in the equation:

$$(1) \quad SQ = \alpha + \beta_1 * ACC + \beta_2 * NAV + \beta_3 * DES + \beta_4 * REL + \beta_5 * ASS + \beta_6 * RES + \beta_7 * CUS + E$$

Where α is an intercept, $\beta_1 - \beta_7$ are the regression coefficients of the independent variables and E represents the error term. Because of considerable correlations among the independent variables (See Table 4), high levels of multicollinearity were expected. The variance inflation factors (VIF) were calculated and found to be in the range of 1.5 – 3.5. In order to better separate the effects of the different independent variables a Ridge-regression was therefore conducted. In case of multicollinearity least squares estimates themselves are unbiased, but their variances are very large and possibly far from the true values. By adding a small bias (k) to the regression estimates, more reliable estimates can be obtained. A value of .6 for k was chosen, as this produced the best results. The regression results are reported in Table 5. From Table 5 it can be concluded that highly significant relationships exist between the two major user interface

dimensions, *navigation* (proposition 2) and *design* (proposition 3), as well as the adapted SERVQUAL dimensions *reliability* (proposition 4) and *customization* (proposition 7), and customer responses.

Please take in Table 5

Weaker, but still significant effects have been found between *accessibility* (proposition 1) and *responsiveness* (proposition 6) and customer responses, while, surprisingly, no significant relationship could be found between *assurance* and customer responses (proposition 5). A large proportion of the variance in customer responses was explained by the six significant constructs (adjusted $R^2 = .71$), while the model has a relatively good and highly significant fit to the data ($F = 32.5405$). This implies that the data support all propositions, except proposition 5.

Discussion and conclusions

As a result of the rapid development of information and communication technologies, customers have gained access to a wide range of new services on the Internet (Porter, 2001). The present study focused on online travel services as one of the largest e-commerce domains (Anckar & Walden, 2000; Clemons *et al.*, 2002). The aim was to investigate the dimensions of online travel service quality, by adapting and extending the SERVQUAL model. We investigated the impact of customization, navigation, responsiveness, reliability, assurance, design and accessibility on online service quality. Where traditional service quality perceptions are based on an evaluation of interactions between service provider and customers, online service quality perceptions appear to be generally based on evaluations of the interaction between the customer and a user interface. Each online service provider employs standardized interfaces and technology for its customers. Delivering online services right the first time every time is crucial. Imperfections in technology or user interface design have immediate consequences for online service quality perceptions. Furthermore, customers' zones of tolerance are likely to be smaller for online services, because a multitude of providers are available on the Web (Parasuraman *et al.*, 1991; Van Riel *et al.*, 2003).

The present study found that all factors, except for assurance, had a significant impact. Our model explained 71% of the variance in online service quality. As we found a weak antecedent role of assurance, the substantial correlation between assurance and customer

responses may point at reverse causality. This observation warrants further investigations. The impact of accessibility and responsiveness on online service quality perceptions was weaker yet significant. The true importance of accessibility may be revealed to its full extent when the customers really need to contact the company, which may not have been the case in the sample used for the research. A similar observation can be made with respect to responsiveness. Customers expect companies to react quickly and accurately to questions, complaints and orders.

Managerial implications and recommendations

Some recommendations for managers of online travel services can be made. Supporting online services have often been considered non-essential and are mainly used to differentiate the service package. We argue that pre-and post-transaction service delivery, which is typically built upon supporting services, may significantly impact overall quality perceptions. In the context of e-commerce, pre- as well as post-transaction services should probably be considered core services, paving the way for future transactions.

The results indicate that both process and outcome dimensions significantly impact service quality perceptions. It is often argued that customer expectations can more easily be exceeded in process than in outcome dimensions (Parasuraman *et al.*, 1991). This is important in relation to online travel services because the interaction between the customer and the website is a process dimension (user interface) and therefore online providers should ensure quality in this area at least as much as in their outcome dimensions (Cox & Dale, 2001). The design of the user interface acts as a business card for the travel agency. User interface quality should be high, because it affects the overall image of the service provider. The navigation aspect of the user interface appears to be essential: Travel sites would gain much by an extremely user-friendly navigation toolbar. Decisions to book a vacation through a travel web site seem to depend on the presence of fast and reliable navigation tools and of an easy-to-use search engine. Cumbersome navigation and search facilities, or processes that are constantly blocked by irrelevant pop-ups and banners, are likely to be detrimental to re-visit and re-use of the website and thus to customer loyalty. The proper use of technology in all aspects of the user interface can be a significant asset of the service provider. Furthermore, technology can contribute to continuous improvement of the online service by studying patterns in the surfing behavior of customers.

Limitations and suggestions for further research

The distinction between pre-transaction, transaction and post-transaction service quality warrants further research. For instance, what is the relative effect of pre- and post-transaction service quality on the perceived overall service quality? The present study largely deals with pre-transaction service quality. Investigating the same customers during the transaction and post-transaction phases would yield new insights into the relative impact of pre-transaction service quality.

Acknowledgements: The authors gratefully acknowledge the contribution of Simone van Leeuwen, who executed the research as a part of the requirements for her Master's Thesis.

Table 1: Importance of online travel services by age group: Means (Std. dev.)

Age	N	Core services			Facilitating services		Supporting services		
		Fast response	Billing	Confirmation	Direct access	E-mail	Country	Stories	Chat room
Early 20's	39	6.6 (0.54)	6.7 (0.44)	6.8 (0.43)	6.1 (1.17)	3.4 (1.63)	5.6 (0.99)	3.1 (1.53)	1.7 (0.80)
Late 20's	23	6.4 (1.24)	6.4 (1.47)	6.2 (1.87)	5.8 (1.65)	3.5 (1.80)	5.0 (1.58)	4.0 (2.12)	2.2 (1.35)
30's and above	29	6.0 (0.98)	6.6 (0.88)	6.7 (0.81)	5.4 (1.52)	4.0 (1.66)	5.28 (1.28)	3.6 (1.40)	2.4 (1.48)

Table 2: Composition of the factors

Items	Factor loading	Cronbach's alpha	KMO
Service quality		.86	.847
The quality of services on the travel agency's website is very good	.75		
On a scale between 1 (very bad) and 7 (very good) I would grade the travel agency's website:	.80		
In general I am very satisfied with the service on this website	.85		
In the future I will certainly make use of the website to search for travel information	.86		
In the future I will certainly make use of the website to book travel	.78		
Navigation		.90	.822
Browsing between pages is easy.			
The structure of the site is logical.			
A good search engine is present.			
Categorization of topics is helpful in finding what I search			
Design		.78	
The site is pleasant to look at.	.63		
The site is original	.63		
There are too many pictures (recoded)	.86		
The use of colors on the site is good	.71		
Accessibility		.81	
The website makes it easy to get into touch with the travel agency	.78		
I can easily find the e-mail address and telephone number of travel24.	.92		
Reliability		.81	.852
The information provided by the travel agency is up-to date.	.86		
I can rely on the information provided on the website.	.75		
Product information (travel description) is accurate	.73		
Responsiveness			
Imagine having a problem, it is easy finding help on the site	.84		
Customization		.85	
The site helps to find exactly what I want.	.64		
The site is easy to customize (by offering the possibility to search on date, destination and price.)	.88		
I can quickly and easily see if they offer something that suits me.	.83		

Table 3: Descriptives for three travel websites: Means (Std. dev.)

	De Jong Intra	Travel 24	D-reizen
Customization (CUS)	3.42 (1.48)	4.64 (1.05)	5.05 (1.16)
Navigation (NAV)	3.74 (1.59)	5.18 (1.12)	5.09 (1.12)
Responsiveness (RES)	3.95 (1.47)	4.11 (1.31)	4.40 (1.16)
Reliability (REL)	4.30 (1.40)	5.04 (1.11)	5.49 (0.79)
Assurance (ASS)	4.87 (1.16)	4.85 (1.29)	5.54 (0.76)
Design (DES)	4.31 (1.48)	4.26 (0.68)	4.87 (1.23)
Access (ACC)	4.10 (1.64)	5.13 (1.35)	4.88 (1.34)
Service Quality (SQ)	3.36 (1.32)	4.51 (0.79)	4.77 (1.15)
