The Role of Public Debt in the Game of Double Chicken

Roel M.W.J. Beetsma

A. Lans Bovenberg

Central Planning Bureau and CEPR

ABSTRACT:

This paper explores how debt accumulation is affected by the strategic interactions between monetary and fiscal authorities. To achieve the second best with a dependent central bank, the government needs to be made both more conservative and more impatient. However, in the absence of political distortions, an optimally designed conservative, independent central bank is sufficient to establish the second best. In the presence of political distortions, however, also an optimal debt target is needed.

Keywords: Central bank independence, price stability weights, (optimal) debt targets, strategic debt management, political distortions, optimal preferences.

1. Introduction

Many countries have experienced substantial increases in public debt over the past two decades. The academic literature has explored public debt accumulation from two different perspectives. One perspective views public debt as a strategic instrument employed by current governments to affect the policies chosen by future governments. Persson and Svensson (1989), Aghion and Bolton (1989) and Alesina and Tabellini (1990) provide illustrations of this approach. Another strand of the literature explores the incentives to accumulate public debt by governments that are unable to commit to an announced inflation rate. Obstfeld (1991a,b) demonstrates that, in the absence of commitment, governments may want to accumulate public assets in order to eliminate the incentives to generate unanticipated inflation, thereby enhancing the credibility of anti-inflation policies.¹

This paper links both strands of the literature by studying the accumulation of public debt both for strategic reasons as well as the purpose of building up credibility. After presenting our two-period model in Section 2, the analysis is conducted in three steps. First, as a benchmark case, Section 3 considers a single, centralized, benevolent policymaker who selects both fiscal and monetary policy and who is able to commit. This benchmark case corresponds to the second-best equilibrium (i.e. the Pareto optimum in the absence of lump-sum taxes).

Section 4 takes the second step by assuming discretion rather than commitment. Debt policy is now affected by the so-called *credibility effect* (conform Obstfeld, 1991a,b),² which induces the government to accumulate additional public assets in order to reduce inflation expectations in the future. In this way, the accumulation of public assets enhances the credibility of future anti-inflation policies.

The final step, taken in Section 5, extends Obstfeld's (1991a,b) analysis by allowing for decentralized monetary policymaking by an independent central bank, which lacks the ability to commit. This allows us to explore the strategic interaction between fiscal and monetary authorities.³ With centralized decision making, the inability to commit unambiguously reduces the accumulation of public debt. With decentralized decision making, in contrast, public debt may be boosted by the strategic interaction between the fiscal and monetary authorities. In particular, if the central bank is too conservative from the ex-ante perspective of the fiscal authority, the latter accumulates

¹ This second perspective on debt accumulation is closely related to the literature investigating how the term structure of public debt can help to establish the optimal commitment equilibrium. See, e.g., Lucas and Stokey (1983), Persson and Svensson (1984), Persson, Persson and Svensson (1987), Calvo and Obstfeld (1990) and Calvo and Guidotti (1992).

² In Obstfeld (1991a,b), time-inconsistency originates in money demand, which depends on expected inflation. Our model, in contrast, is in the tradition of Barro and Gordon (1983a,b). In particular, non-indexed nominal wages are the source of time inconsistency.

³ For the interactions between monetary and fiscal policies in a closed economy, see Sargent and Wallace (1981), Tabellini (1986), Alesina and Tabellini (1987), Debelle (1993), Levine and Pearlman (1992), Levine (1993), Debelle and Fischer (1994), Levine and Brociner (1994) and Krichel, Levine and Pearlman (1994).

additional debt to encourage the central bank to produce higher future inflation. However, if the first-period fiscal authorities do not find the central bank conservative enough, they strategically reduce debt accumulation to induce the central bank to decrease inflation in the future. In this way, rather paradoxically, the discretionary equilibrium may result in a better performance in terms of long-run price stability than the commitment equilibrium, which produces less inflation in the short run. This result is closely related to Sargent and Wallace (1981) who show, with exogenously given fiscal policy, that tighter monetary control in the short run may boost inflation in the longer run. We demonstrate how this result may continue to hold in an explicit game-theoretic framework in which both monetary and fiscal policy are endogenously determined.

The strategic interaction between monetary and fiscal authorities in a dynamic framework allows us to deal with not only positive issues (including the impact on public debt and inflation over time) but also normative issues. In particular, the inability to commit gives rise to two additional sources of welfare losses compared to the second best. One, familiar source is intratemporal: the monetary authorities attempt to alleviate distortions in the real economy by stimulating output through unanticipated inflation. With the private sector anticipating these attempts, however, monetary policy is ineffective in boosting output in equilibrium. Accordingly, the equilibrium inflation rate exceeds the socially optimal rate.

The other, less familiar, source of welfare loss produced by discretionary policy involves the intertemporal distribution of distortionary losses. From the perspective of a discretionary policymaker who sets policy in the first period, first-period expectations are pre-determined. The corresponding expectations in the second period, in contrast, still have to be determined and thus can be affected by policy. This induces the policymaker to use unanticipated inflation in the first period, thereby in effect exploiting the exogenous first-period inflation expectations, to impact inflation expectations in the second period. However, in equilibrium, the private sector correctly anticipates these incentives facing policymakers to use first-period unanticipated inflation in this way. In a dynamic model, therefore, the inability to commit yields not only intra- but also intertemporal distortions.

These welfare losses can be eliminated by properly designed institutions. Adjusting monetary policy preferences is the most direct way to deal with the distortions due to the inability to commit. Indeed, with an independent central bank (i.e. decentralized monetary policymaking) and in the absence of political distortions, both sources of welfare loss vanish if the central bank's price stability weight is adjusted optimally. Intuitively, the incentive facing the first-period fiscal authorities to use debt policy strategically originates in sub-optimal monetary policies in the second period. If the central bank features the optimal preferences from a social point of view, the fiscal authorities no longer perceive the need to use debt policy to bring future monetary policy closer to the optimum. With a dependent central bank (i.e. centralized policymaking), the government needs to be made not only more inflation averse than an independent central bank but also more impatient than society.

If political distortions cause the preferences of the fiscal authorities to depart from those of society, an optimally designed, conservative independent central bank is no longer sufficient to reach the second best. Intuitively, changing monetary institutions is not the proper instrument to deal with imperfect fiscal institutions. Indeed, to achieve the second best in the presence of political distortions, not only monetary but also fiscal institutions should be dealt with. In particular, properly adjusting the price stability weight of the central bank removes the distortions due to the inability to commit while debt ceilings avoid excessive debt accumulation by myopic fiscal authorities who are more impatient than society or by opportunistic authorities who care less about price stability than society does. In this way, institutional arrangements for monetary and fiscal policy are targetted directly at the distortions due to the inability to commit and the existence of imperfect fiscal institutions.

If fiscal instruments, including debt ceilings, are not available, monetary institutions have to deal with fiscal imperfections. If fiscal authorities are more impatient than society, for example, the central bank should be made less conservative than in the absence of political distortions. This in order to encourage the myopic fiscal authorities to restrain debt accumulation so as to enhance the credibility of monetary policy. Accordingly, monetary policy is distracted from its primary mission (i.e. price stability) because it is used as an indirect instrument to deal with imperfections in fiscal policy. This explains why central bankers are strong advocates of ceilings on public debt when designing institutions for the European Monetary Union (EMU).

2. The model

This section formulates a two-period model with homogeneous product markets and a unionized labour market. Within this framework, we set up a game between three players: a union representing workers and two policy authorities, namely a fiscal authority (the government) and a monetary authority (the central bank).

2.1. Output and preferences

The sole objective of unions is to achieve a target real wage rate, the logarithm of which we normalize to zero.⁴ Therefore, the (log) of the nominal wage rate in period t is set equal to the (rationally) expected (log) price level in period t , p_t^e . Nominal wage contracts are signed before policy is selected. Unions thus act as Stackelberg leaders vis-à-vis policymakers.

Output is given by $Y_t = L_t^\eta$ ($0 < \eta < 1$), where L_t is labor, and is taxed at a rate τ . The representative firm selects employment so as to maximize profits $P_t L_t^\eta (1 - \tau_t) - W_t L_t$, where P_t and W_t

⁴ For similar approaches, see Alesina and Tabellini (1987), Debelle (1993), Debelle and Fischer (1994) and Jensen (1994).

denote the price level and the wage rate, respectively. Hence, (log) output is given by $y_t = (\eta/(1-\eta))(\pi_t - \pi_t^e - \tau_t + \log \eta)$, where π_t is the inflation rate and π_t^e the expected inflation rate. For convenience, we normalize output by subtracting the constant $(\eta/(1-\eta))\log \eta$ from y_t . Hence, normalized output, x_t , amounts to

$$x_t = v(\pi_t - \pi_t^e - \tau_t), \quad v \equiv \eta/(1-\eta). \quad (2.1)$$

Without tax distortions, $x_t=0$ in a rational expectations equilibrium (where inflation is anticipated, i.e. $\pi_t = \pi_t^e$, see (2.1)). In addition to distortionary output taxes, we allow for other, non-tax, distortions due to, for example, union power in the labor market or monopoly power in commodity markets. The first-best output level, i.e. output with neither tax nor non-tax distortions, is denoted by $\tilde{x}_t$. Thus, $\tilde{x}_t > 0$ measures the non-tax distortions and can be interpreted as an *implicit* tax on output. In fact, by offsetting the implicit output tax, an output subsidy ($\tau_t = -\tilde{x}_t/v$) can raise output towards its first-best level $\tilde{x}_t$.

Society features a social welfare function that differs from the objectives of the unions because the social welfare function accounts for the preferences of not only workers but also non-workers. In particular, society's preferences, defined over inflation, output and public spending, are represented by the following loss function,

$$V_S = \frac{1}{2} \sum_{t=1}^{\infty} \beta_S^{t-1} [\alpha_{\pi S} \pi_t^2 + (x_t - \tilde{x}_t)^2 + \alpha_{gS} (g_t - \tilde{g}_t)^2], \quad 0 < \beta_S \leq 1, \quad \alpha_{\pi S}, \alpha_{gS} > 0. \quad (2.2)$$

Welfare losses increase in the deviations of inflation, (log) output and government spending (g_t is government spending as a share of non-distortionary output) from their targets (or first-best levels or 'bliss points').⁵ The target level of inflation corresponds to price stability. The non-distortionary output level, $\tilde{x}_t$, represents the bliss point for output. The first-best level of government spending, $\tilde{g}_t$, can be interpreted as the optimal share of non-distortionary output to be spent on public goods if (non-distortionary) lump-sum taxes would be available (see Debelle and Fischer, 1994). The parameters $\alpha_{\pi S}$ and α_{gS} correspond to the weights of the price stability and government spending objectives, respectively, relative to the output objective. The limiting case of $\alpha_{gS} \rightarrow \infty$ corresponds to the situation where government spending is exogenously fixed at $\tilde{g}$. Finally, β_S denotes society's subjective discount factor.

Preferences of the fiscal and monetary authorities are likewise given by, respectively,

$$V_F = \frac{1}{2} \sum_{t=1}^{\infty} \beta_F^{t-1} [\alpha_{\pi F} \pi_t^2 + (x_t - \tilde{x}_t)^2 + \alpha_{gS} (g_t - \tilde{g}_t)^2], \quad 0 < \beta_F \leq 1 \text{ and } \alpha_{\pi F} > 0. \quad (2.3)$$

and

$$V_M = \frac{1}{2} \sum_{t=1}^{\infty} \beta_S^{t-1} [\alpha_{\pi M} \pi_t^2 + (x_t - \tilde{x}_t)^2 + \alpha_{gS} (g_t - \tilde{g}_t)^2], \quad \alpha_{\pi M} > 0. \quad (2.4)$$

⁵ Employment is directly related to output through the production function. Hence, instead of output, employment could have been included as an argument in the loss function, with the target employment level corresponding to the output level in absence of any distortions.

The price stability weights of the two policy authorities do not have to coincide. Moreover, these weights can differ from society's price stability weight. A policymaker with a higher price stability weight will be termed to be *more conservative*. Political distortions are present if the government's preferences depart from society's. In particular, a government that cares less about inflation than society does (i.e. $\alpha_{\pi F} < \alpha_{\pi S}$) is called *opportunistic*. A government is *myopic* if its subjective discount factor is lower than that of society (i.e. $\beta_F < \beta_S$). Such a high rate of time preference may be due to, for example, a high probability of being voted out of office at the end of the first period.⁶

2.2. The government financing requirement

The government budget constraint in each period is given by (see, e.g., Beetsma and Bovenberg, 1995)

$$g_t + (1+\rho)d_{t-1} = \tau_t + \kappa\pi_t + d_t, \quad t=1,2, \quad (2.5)$$

where ρ denotes the (constant) real interest rate⁷ and τ_t and $\kappa \geq 0$ represent, respectively, distortionary tax revenue and real money holdings as shares of (non-distortionary) output.⁸ Seigniorage revenues equal $\kappa\pi_t$. Furthermore, d_{-1} stands for the stock of public debt carried over from the previous period, while d_t denotes newly issued public debt. All public debt is real and matures after one period. Moreover, all debt is paid off at the end of the second period (i.e. $d_2=0$).

The government budget constraint in both periods can be consolidated into a single intertemporal government budget constraint,

$$(1+\rho)d_0 + g_1 + g_2/(1+\rho) = \tau_1 + \kappa\pi_1 + (\tau_2 + \kappa\pi_2)/(1+\rho). \quad (2.6)$$

The left-hand side of (2.6) represents discounted public spending (including repayment of the initial stock of debt). Discounted public revenues are given by the right-hand side of (2.6). For later convenience, we derive what we term the *government financing requirement*, by rewriting (2.5) as

$$\text{GFR}_t \equiv K_t + (1+\rho)d_{t-1} - d_t = [\tau_t + \tilde{x}_t/v] + \kappa\pi_t + [\tilde{g}_t - g_t], \quad \text{where } K_t \equiv \tilde{g}_t + \tilde{x}_t/v. \quad (2.7)$$

⁶ Cukierman, Edwards and Tabellini (1992) show explicitly how the degree of political instability affects the effective rate of time preference of the government in a model in which the choice of the efficiency of the tax structure plays a similar strategic role as debt does in this paper.

⁷ This is the rate of return on public debt required by a risk neutral investor who has an outside investment opportunity paying a real rate of return ρ .

⁸ Alesina and Tabellini (1987), Debelle (1993) and Jensen (1994), among others, assume that $\kappa=1$. However, as will become clear below, non-unitary values for κ play an important role in our analysis.

The government financing requirement (GFR_t) amounts to the government spending target $\tilde{g}_t$, a labor subsidy aimed at offsetting the implicit tax on output, $\tilde{x}_t/v$, and the cost of servicing outstanding public debt net of newly issued debt, $(1+\rho)d_{t-1}-d_t$. The last right-hand side of (2.7) represents the sources of finance: explicit and implicit tax revenues, $\tau_t+\tilde{x}_t/v$, seigniorage revenues, $\kappa\pi_t$, and the shortfall of government spending from its target, $\tilde{g}_t-g_t$.

If we take the discounted (to period 1) sums of the left and right hand sides of (2.7) (for $t=1,2$), we obtain the *intertemporal government financing requirement*,

$$F \equiv (1+\rho)d_0 + K_1 + K_2/(1+\rho) = \sum_{t=1}^2 (1+\rho)^{-(t-1)} [(\tau_t+\tilde{x}_t/v)+\kappa\pi_t+(\tilde{g}_t-g_t)]. \quad (2.8)$$

3. Centralized policymaking with commitment

In this section, the central bank is dependent. Accordingly, the government selects not only tax rates and public spending but also inflation. Furthermore, as a benchmark for the more realistic, discretionary equilibria analyzed below, this section assumes that the government is able to commit. The government thus credibly announces its monetary policy each period before expectations are formed. Therefore, expectations are perceived to be endogenous not only in the second but also in the first period, so that the government takes into account the rational expectations constraint ($\pi_t^e = \pi_t$) in both periods.⁹ With a benevolent government (i.e. a government that shares society's preferences), commitment leads to the second best (i.e. the Pareto optimum in absence of lump-sum taxes).

We can solve for the commitment equilibrium by working backwards in time.¹⁰ The policy outcomes and welfare losses in the second period are computed for given d_1 , and therefore coincide with the corresponding outcomes in what we will refer to in the following as the *static (version of the) model* (i.e. the single-period version of the model with an exogenous stock of public debt d_1 ; see Beetsma and Bovenberg, 1995). The government's second period welfare losses are (given d_1 and given that the second period policy instruments are selected optimally) is $\frac{1}{2}P^{-1}[K_2 + (1+\rho)d_1]^2$, where $P \equiv \kappa^2/\alpha_{\pi F} + 1/v^2 + 1/\alpha_{gS}$. Hence, substituting (2.1) into (2.3) and imposing $\pi_1^e = \pi_1$, the first-period Lagrangian, to be optimized over π_1 , τ_1 , g_1 and d_1 , amounts to

$$\begin{aligned} \mathcal{L} = & \frac{1}{2}[\alpha_{\pi F}\pi_1^2 + (v\tau_1 + \tilde{x}_1)^2 + \alpha_{gS}(g_1 - \tilde{g}_1)^2] + \frac{1}{2}\beta_F P^{-1}[K_2 + (1+\rho)d_1]^2 + \\ & \lambda_1[g_1 + (1+\rho)d_0 - \tau_1 - \kappa\pi_1 - d_1], \end{aligned} \quad (3.1)$$

where λ_1 represents the marginal costs of public funds (i.e. the Lagrange multiplier of the government budget constraint). Optimizing the Lagrangian above, we arrive at the following first-order conditions for inflation, taxation, public spending and public debt, respectively,

$$\alpha_{\pi F}\pi_1 = \lambda_1\kappa, \quad (3.2)$$

$$v(v\tau_1 + \tilde{x}_1) = \lambda_1, \quad (3.3)$$

$$\alpha_{gS}(\tilde{g}_1 - g_1) = \lambda_1, \quad (3.4)$$

$$\beta_F P^{-1}[K_2 + (1+\rho)d_1](1+\rho) = \lambda_1. \quad (3.5)$$

Public debt

Combining (3.2)-(3.4) with the government financing requirement (2.7) for the first period, we find

⁹ In the discretionary equilibria analyzed below, in contrast, first-period expectations are perceived to be exogenously given when policy is set in the first period. The same holds true for the second period expectations when policies are set in the second period.

¹⁰ Appendix A provides a complete derivation of the equilibrium outcomes.

$v(v\tau_1 + \tilde{x}_1) = P^{-1} [K_1 + (1+\rho)d_0 - d_1]$. Substituting this into (3.3) and combining with (3.5), we arrive at

$$[K_1 + (1+\rho)d_0 - d_1] = \beta_F(1+\rho)[K_2 + (1+\rho)d_1]. \quad (3.6)$$

The left hand side of (3.6) represents the marginal benefit in the first period of issuing more debt, while the right hand side represents the (discounted) marginal cost in the form of larger distortionary losses in the second period on account of the higher debt servicing costs. Other things equal, the discounted cost is lower, the lower the discount factor β_F . Due to the quadratic specification of the loss function, the marginal benefit (in the first period) associated with an increase in debt at the end of the first period is decreasing in d_1 , while the marginal cost (in the second period) of such an increase is increasing in d_1 .

We can rewrite (3.6) as follows:

$$[\beta_F^*(1+\rho)+1] d_1 = [K_1 + (1+\rho)d_0 - K_2] + (1-\beta_F^*)K_2, \text{ where } \beta_F^* \equiv \beta_F(1+\rho). \quad (3.7)$$

The right hand side of (3.7) reveals the two determinants of debt accumulation under commitment. The term between square brackets represents the so-called *smoothing effect*. This effect raises (reduces) d_1 whenever the exogenous component of the government financing requirement in the first period, $K_1 + (1+\rho)d_0$, exceeds (falls short of) the exogenous component of the government financing requirement in period two, K_2 .

The second term at the right hand side of (3.7) stands for the *intertemporal substitution effect*. This effect raises (reduces) public debt if impatience as measured by the subjective rate of time preference exceeds (falls short of) the rate of return on assets. For later convenience, we note from (3.7) that d_1 is decreasing in β_F^* , i.e. $\partial d_1 / \partial \beta_F^* < 0$.

Inflation, taxes, and public spending

The policy outcomes are contained in Table 1. The shares of the government financing requirement (GFR) absorbed by seigniorage ($\kappa\pi_t$), the sum of explicit and implicit taxes ($\tau_t \tilde{x}_t / v$) and the public spending gap ($\tilde{g}_t - g_t$) are the same in each period and are, in fact, equal to the corresponding shares in the static version of the model (see Beetsma and Bovenberg, 1995, Table 1 (where $v=1$)). If $\beta_F^*=1$, the government financing requirements are perfectly smoothed out over both periods. Hence, inflation, total taxes and the public spending gap are constant over time. If $\beta_F^*<1$, first-period welfare losses are relatively important compared to the return on assets. Accordingly, inflation, seigniorage, taxes and the government spending are rising over time.¹¹

Welfare

¹¹ The model predicts that the financing sources of the government move jointly over time (cf. Mankiw, 1987).

Society's discounted social welfare loss contained in Table 2 is derived by substituting the policy outcomes from Table 1 into expression (2.2) and using that, in equilibrium, $\pi_t^e = \pi_t$, $t=1,2$. The term between the first square brackets in the welfare expression in Table 2 stems from the *intratemporal* distribution of distortionary losses and reaches a minimum for $\alpha_{\pi F} = \alpha_{\pi S}$. The term between the second square brackets (i.e. $\delta_C^2((\beta_C^*)^2 + \beta_S)$, where $\delta_C = (1+\rho)/(\beta_C^*(1+\rho)+1)$ and $\beta_C^* = \beta_F^*$, and where the subscript C denotes the regime of "centralized commitment") originates in the *intertemporal* distribution of distortionary losses and reaches a minimum for $\beta_F = \beta_S$.¹² Hence, with commitment, the second best (i.e. the Pareto optimum in absence of lump-sum taxes) is reached if the government's preferences coincide with society's. Political distortions result in additional welfare losses.

The optimal debt target

In the United States, a number of recent proposals have been put forward to balance the federal public budget. Furthermore, the Maastricht treaty includes ceilings on public debt as entrance requirements for the EMU. We now explore the welfare effects of a debt target within the framework of our model. In the presence of a target $\hat{d}_1$ on public indebtedness, the government solves two single period optimisation problems with exogenous government financing requirements $\tilde{K}_1 + (1+\rho)d_0 - \hat{d}_1$ and $\tilde{K}_2 + (1+\rho)\hat{d}_1$ in the first and second period, respectively. Given that inflation, taxes and public spending are selected optimally by the policymaker in each period, society's discounted welfare loss amounts to

$$\frac{1}{2P} \left(\left(\tilde{K}_1 + (1+\rho)d_0 - \hat{d}_1 \right)^2 + \beta_S \left(\tilde{K}_2 + (1+\rho)\hat{d}_1 \right)^2 \right). \quad (3.8)$$

A lower debt target $\hat{d}_1$ shifts welfare losses from the second towards the first period. The optimal debt target minimises the term between brackets and is thus given by¹³

$$\hat{d}_1^{\text{opt}} = \frac{\tilde{K}_1 + (1+\rho)d_0 - \tilde{K}_2 + (1-\beta_S^*)\tilde{K}_2}{\beta_S^*(1+\rho)+1}, \text{ where } \beta_S^* = \beta_S(1+\rho). \quad (3.9)$$

In fact, a debt target equal to $\hat{d}_1^{\text{opt}}$ implies an optimal intertemporal allocation of distortions, so that the economy attains the second best if $\alpha_{\pi F} = \alpha_{\pi S}$. For a government featuring a discount factor $\beta_F = \beta_S$, $\hat{d}_1^{\text{opt}}$ equals d_1 implied by (3.7). Hence, in the absence of political distortions, arbitrary (in contrast to the optimal) debt targets are costly. With myopic policymakers, however, the imposition of the optimal debt enhances welfare by protecting society from excessive debt accumulation by a myopic

¹² The function $(1+\rho)^2(z^2 + \beta_S)/(z(1+\rho)+1)^2$ is decreasing in z for $z < \beta_S(1+\rho)$, increasing for $z > \beta_S(1+\rho)$ and, hence, attains a global minimum for $z = \beta_S(1+\rho)$. Therefore, the second component of the welfare loss is minimized for $\beta_F^* = \beta_F(1+\rho) = \beta_S(1+\rho)$, hence for $\beta_F = \beta_S$.

¹³ $\hat{d}_1$ does not interact with the intratemporal allocation of distortions. Therefore, (3.9) describes the optimal debt target also if the policymaker is opportunistic ($\alpha_{\pi F} < \alpha_{\pi S}$).

policy maker ($\beta_F < \beta_S$).

4. Centralized policymaking with discretion

In this section, the central policymaker is not able to commit. When discretionary policies are selected in the first period, inflation expectations for that period are taken to be exogenously given because the private sector acts as a Stackelberg leader in concluding nominal wage contracts. However, expectations of second period inflation still need to be formed and, hence, can be affected by first-period policy. Indeed, as we will see below, the government may want to use its debt policy to affect second-period inflation expectations.

Public debt

Employing a similar procedure as in the case of centralized commitment (in Section 3), we find the optimal debt level from the following first-order condition for public debt:

$$[\mathbb{K}_1 + (1+\rho)d_0 - d_1] = \beta_F(1+\rho)(D^*/D)[\mathbb{K}_2 + (1+\rho)d_1], \quad (4.1)$$

where $D \equiv \kappa(\kappa+1)/\alpha_{\pi F} + 1/v^2 + 1/\alpha_{gS}$ and $D^* \equiv (\kappa+1)^2/\alpha_{\pi F} + 1/v^2 + 1/\alpha_{gS}$. As in the corresponding expression (3.6) in Section 3, the left-hand side of (4.1) represents the marginal benefit (in period one) from issuing more debt, while the right-hand side stands for the marginal cost (in period two). By comparing (3.6) from the commitment equilibrium with (4.1) from the discretionary equilibrium, we observe that discretionary debt accumulation is affected by another effect in addition to the smoothing and intertemporal substitution effects. This so-called *credibility effect*, which arises from the inability to commit, is represented by the factor $D^*/D > 1$ at the right-hand side of (4.1). This factor effectively increases the discount factor, thereby raising the second-period costs associated with additional debt. Therefore, with centralisation, the stock of public debt, d_1 , is in general lower under discretion than under commitment (recall that $\partial d_1 / \partial \beta_F^* < 0$).

The intuition for the lower stock of debt in the discretionary equilibrium is the following (see also Obstfeld, 1991a,b). Whereas first-period inflation expectations are perceived as given by the policymaker when selecting debt policy, second-period inflation expectations can still be affected. Hence, to reduce the "stock of credibility problems" in the second period, as measured by the government financing requirement $\mathbb{K}_2 + (1+\rho)d_1$, the government reduces public debt, thereby mitigating the inflationary bias in the second period. In other words, the government trades off additional distortionary losses in the first period against gains in credibility of monetary policy in the second period.

The inability to commit exerts a large effect on debt policy if anti-inflation monetary policy is not very credible. A steep slope of the Phillips curve (i.e. a large v) harms the credibility of anti-inflation policies because it raises the boost to output from inflation surprises. Accordingly, it

requires more asset accumulation to build up credibility. Similarly, a high priority for public spending (i.e. a large weight α_{gs}), by requiring higher output taxes, raises the incentive to use unanticipated inflation to alleviate tax distortions and, hence, also boosts asset accumulation. High priority to price stability (i.e. a large weight $\alpha_{\pi F}$) raises second-period credibility of low inflation policies, thereby reducing the need to accumulate public assets (note that $\beta_D^* \equiv \beta (1+\rho)(D^*/D)$ is decreasing in $\alpha_{\pi F}$). In fact, if $\alpha_{\pi F} \rightarrow \infty$, second period inflation and, therefore, also the second period inflation bias, are zero, irrespective of the size of the government financing requirement. In that case, the first-period government sees no need to accumulate assets for the purpose of building up credibility. In other words, a high price stability weight of the government substitutes for asset accumulation in enhancing the credibility of second-period monetary policy.

Inflation

The accumulation of public assets shifts distortionary losses from the second to the first period. In the special case of $K_1=K_2$, $d_0=0$ and $\beta_F^*=1$, policy variables are constant over time under commitment. Under discretion, in contrast, inflation and taxation are falling over time¹⁴ while government spending and output are rising.

Assume for the moment that $\alpha_{\pi F}=\alpha_{\pi S}$. In the static version of the model, inflation is higher under discretion than under commitment. However, the incentive to build up additional public assets in the dynamic model of this paper implies that distortionary losses are shifted away from the second to the first period. This may reverse the "standard" ranking. In particular, second-period inflation is lower under discretion than under commitment, if (see Appendix B),

$$\left(\frac{\beta_F^*(1+\rho)}{\beta_F^*(1+\rho)+1} \right) \left(\frac{\kappa(\kappa+1)}{\alpha_{\pi S}(1/v^2+1/\alpha_{gs})} \right) > 1. \quad (4.2)$$

This condition is met if the negative effect on second-period inflation associated with the accumulation of public assets on account of the credibility effect dominates the familiar inflation bias due to discretion. Accordingly, condition (4.2) is more likely to be met if the credibility effect is important. As explained above, this is the case if the Phillips curve is steep and society attaches a low priority to price stability compared to public spending. Large money holdings, κ , make

¹⁴ This is related to a result on optimal capital taxation due to Chamley (1986). He finds that the optimal policy of a government is to reduce the tax rate on capital over time. The reason is that the initial stock of capital is inelastically supplied. Here, a similar effect arises. Since inflation expectations in existing wage contracts are perceived to be "inelastic", the government finds it optimal to impose a high initial inflation tax, which contributes to the accumulation of assets and builds up credibility of future policy. However, our set up differs fundamentally from that of Chamley (1986). In particular, policies are time consistent in the current model because inflation expectations are endogenous and rational in equilibrium. Hence, the private sector correctly anticipates the incentives of the public sector to impose a high inflation tax in the short run. This is in contrast to Chamley (1986), who assumes that the stock of capital is exogenously fixed in the short run and thus not affected by the incentive facing the government to tax the capital stock in the short run. In Chamley (1986), who assumes commitment, the derived policy is socially optimal, given the absence of lump-sum taxes. As is explained below, the time-consistent equilibrium derived in the current paper is not optimal.

condition (4.2) easier to satisfy by reducing the importance of the traditional inflation bias under discretion.¹⁵ In particular, even under commitment, authorities rely relatively heavily on seigniorage to cover their financing requirement if money holdings are large. More generally, condition (4.2) reveals that tighter short-run monetary policy (under commitment) may yield higher inflation (compared to discretion) in the long run if large money holdings imply that inflation exerts powerful effects on the public finances.

Welfare

An expression for the welfare loss is contained in Table 2. Just like in the commitment case, the welfare loss can be decomposed in *intra*temporal losses (the term in the first square brackets) and an *inter*temporal losses (the term in the second square brackets).

If the government's preferences coincide with society's, both of these losses under discretion exceed the corresponding second-best losses under commitment. As regards the *intra*temporal loss, we have

$$\left(\frac{\frac{(\kappa+1)^2}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{\left(\frac{\kappa(\kappa+1)}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right)^2} \right) > \left(\frac{1}{\frac{\kappa^2}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}} \right), \quad (4.3)$$

where the left-hand and right-hand sides represent the *intra*temporal losses under discretion and commitment, respectively. The additional *intra*temporal losses under discretion originate in the incentives of the government to employ inflation surprises as an instrument to alleviate tax distortions. The private sector correctly anticipates these incentives of the government to exploit nominal contracts. In this way, the interaction between the government, which cannot commit to a low-inflation policy, and the public, which correctly anticipates inflation, generates an inflation bias.

Whereas the *intra*temporal welfare loss due to discretion is relatively familiar from the literature, the second, *inter*temporal welfare loss is less well known. The following inequality indicates the suboptimality of the *inter*temporal allocation under discretion¹⁶

$$\frac{(1+\rho)^2(\beta_D^* + \beta_S)}{(\beta_D^*(1+\rho) + 1)^2} > \frac{(1+\rho)^2(\beta_S^* + \beta_S)}{(\beta_S^*(1+\rho) + 1)^2}, \quad (4.4)$$

¹⁵ Condition (4.2) is more likely to be met also if the policymaker is more patient, so that he attaches more weight to second period welfare losses. In that case, most of the *inter*temporal financing requirement is met in the first period so that a shift in the financing requirement from the second towards the first period exerts a relatively large impact on second-period policy outcomes.

¹⁶ To derive this inequality, we use footnote 11.

where β_D^* is defined in Table 1 and evaluated at $\alpha_F = \alpha_S$ and $\beta_F = \beta_S$, while β_S is defined in (3.9). The intuition for the additional intertemporal welfare losses produced by discretion is as follows. From the perspective of a discretionary policymaker who sets policy in the first period, first-period expectations are pre-determined. The corresponding expectations in the second period, in contrast, still have to be determined and thus can be affected by (debt) policy. This induces the policymaker to rely relatively heavily on first-period financing, among other things in the form of unanticipated inflation, in order to reduce inflation expectations in the second period. However, in equilibrium, the private sector correctly anticipates the incentives of the government to use inflation surprises in the first period so as to build up assets in order to enhance the credibility of monetary policy in the second period. Hence, the discretionary equilibrium suffers from an asset bias associated with an excessive reliance on first-period sources of financing (if $\beta_F = \beta_S$). From society's point of view, inflation expectations are endogenous in not only the second period but also the first period. Hence, as under commitment, only smoothing of distortions and inter-temporal substitution effects (and not the credibility effect) should determine optimal debt policy.

Optimal institutions

To establish the second best, two additional distortions should offset, respectively, the *intra*temporal and the *inter*temporal misallocation of distortionary losses. As in the static version of the model, the optimal intratemporal trade-off is attained if

$$\alpha_{\pi F} = \alpha_{\pi F}^{\text{opt}} \equiv \alpha_{\pi S}(\kappa + 1)/\kappa. \quad (4.5)$$

This value of $\alpha_{\pi F}$ minimises the intratemporal welfare losses (i.e. the term in the first pair of square brackets in Table 2). The government has to be made more conservative than society (i.e. more inflation averse as measured by a higher value of $\alpha_{\pi F}$) in order to offset the inflation bias due to discretion (see Rogoff, 1985).

In contrast to the static model and also in contrast to the case with decentralized decision making analyzed in Section 5 below, fiscal policy still does not face the correct incentives, even if the degree of inflation aversion is corrected according to (4.5). Intuitively, the adjustment of monetary preferences distorts intertemporal decisions. In particular, given their high inflation aversion (set according to (4.5)), the policymakers still perceive an inflationary bias in the second period, even though inflation is optimal from the point of view of society, which features a lower price stability weight than policymakers. Hence, they accumulate assets to bring inflation performance in the second period in line with their own preferences rather than those of society.

The intertemporal distortions can be eliminated in two ways. One is to adjust the subjective discount factor of the policymaker (for example, by an appropriate choice of the probability of dismissal after the first period). In particular, the second best is reached, if, in addition to (4.5), we set

$$\beta_F^{\text{opt}} = \beta_S \left(\frac{\frac{\kappa^2}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{\frac{\kappa(\kappa+1)}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}} \right) < \beta_S. \quad (4.6)$$

The government thus must be made less patient than society. If governments are myopic (due to, e.g., short election cycles), this does not imply that the government necessarily has to be made less patient than it in fact is. In particular, (4.6) requires an increase in the degree of patience if governments are much less patient than society and if the optimal discount factor does not depart much from society's (so that $\beta_F < \beta_F^{\text{opt}}$). This latter condition is met if money holdings are small, the Philipscurve is relatively flat, and society attaches a high priority to price stability and a low priority to public spending. Under these conditions, the credibility effect is only small because policymakers do not perceive much of a need to enhance the credibility of future anti-inflation policies. These conditions for the credibility effect to be small are likely to be met in modern democracies, which tend to be characterized by small money holdings, large inflation aversion (Collins and Giavazzi, 1993), and impatient authorities due to short election cycles.

A second way to correct the intertemporal trade-off is to impose a debt target. The optimal debt target, which can be found by the minimisation of an expression similar to (3.8) (see Appendix C) can be chosen independently from the optimal inflation weight (4.5). Again, the optimal debt target is given by the optimal amount of debt d_1 under commitment (3.9). In combination with the adjustment of $\alpha_{\pi F}$ to $\alpha_{\pi F}^{\text{opt}}$ according to (4.5), the debt target yields the second best.¹⁷

5. Decentralized policymaking with an independent central bank

In this section, policymaking is decentralized. In particular, the government takes as given the current inflation rate and selects only taxes, public spending and public debt. Monetary policy is delegated to an independent central banker, who is unable to commit and who selects the inflation rate, taking as given the policy choices of the government. In this case, the fiscal authority in the first period acts as a leader vis-à-vis the three players (including itself) in the second period. Hence, as we will see below, the fiscal authority may want to use debt strategically in the first period in order to affect expectations and policy decisions in the second period.

Public debt accumulation

¹⁷ If $\beta_F = \beta_S$, (3.9) puts a limit on asset accumulation rather than debt accumulation as advocated in the Maastricht Treaty for an EMU or in the proposed balanced budget amendments in the United States. However, a debt ceiling may be desirable if β_F is much lower than β_S .

A full derivation of the equilibrium is contained in Appendix D. As before, the government sets the optimal debt level d_1 by equating the marginal benefit and the marginal cost from issuing more debt

$$[K_1 + (1+\rho)d_0 - d_1] = \beta_F(1+\rho)(N_D^*/N_D)[K_2 + (1+\rho)d_1], \quad (5.1)$$

where $N_D = \kappa/\alpha_{\pi M} + 1/v^2 + 1/\alpha_{gS}$ and $N_D^* = \alpha_{\pi F}/\alpha_{\pi M}^2 + 1/v^2 + 1/\alpha_{gS}$. Debt accumulation is again characterized by the smoothing and intertemporal substitution effects. In particular, if $\alpha_{\pi F}/\alpha_{\pi M} = \kappa$ (and, hence, $N_D^*/N_D = 1$), debt accumulation coincides with that under centralized commitment.

As in the case of centralized discretion, however, a third effect impacts debt policy. This so-called *strategic effect* originates in disagreement between the first-period fiscal authority and the second-period monetary authority about second-period inflation. This disagreement causes the fiscal authority in the first period to strategically employ debt policy in order to affect second-period monetary policy.

For example, if the government cares much less about inflation than the monetary authority does (so that $\alpha_{\pi F}/\alpha_{\pi M} < \kappa$ and, hence, $N_D^*/N_D < 1$, thereby reducing the effective discount factor of the fiscal authority, $\beta_{ND}^* \equiv \beta_F^* N_D^*/N_D$, below β_F^*), the government strategically raises debt in the first period in order to encourage the central bank to raise inflation in the second period.¹⁸ Higher debt raises second-period inflation because the associated higher debt service requires higher taxes in the second period. This reduces second-period output, thereby tempting the central bank to boost output by the way of unanticipated inflation.¹⁹

If the fiscal authority attaches a sufficiently high priority to price stability (compared to that of the central bank), the fiscal authority may want to reduce rather than raise debt strategically. In particular, the government reduces debt strategically if the central bank is not conservative enough from the ex-ante perspective of the fiscal authority (i.e. $\alpha_{\pi F}/\alpha_{\pi M} > \kappa$ and, hence, $N_D^*/N_D > 1$) so that second-period monetary policy suffers from an inflation bias from that ex-ante perspective. In that case, as a substitute for a sufficiently conservative central bank, the government reduces public debt in order to establish the credibility of anti-inflation policies in the second period.

This suggests that the government accumulates more debt if a conservative, independent

¹⁸ These results on decentralized discretion contrast sharply with those on centralized discretion. In particular, Section 4 showed that with centralized discretion the government always reduces debt to affect future inflation expectations (see also Obstfeld, 1991a,b). With decentralized discretion, in contrast, the government may want to raise rather than reduce debt for this purpose.

¹⁹ The strategic use of debt in a dynamic model implies that the price stability weight of the government affects the equilibrium and, in particular, the inflation performance. In the static model, in contrast, the price stability weight of the government does not affect the decentralized equilibrium with discretion (see Beetsma and Bovenberg, 1995).

central bank reduces the need to establish the credibility of anti-inflation policies.²⁰ To explore this issue, we compare debt accumulation under decentralized and centralized discretion. An independent central bank (i.e. decentralized policymaking) yields more debt accumulation if and only if $\beta_D^* > \beta_{ND}^* \equiv \beta_F(1+\rho)N_D^*/N_D$ or $D^*/D > N_D^*/N_D$. This condition reduces to (see Appendix E),

$$\left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \left(\frac{(\kappa+1)}{\alpha_{\pi F}} + \frac{1}{\alpha_{\pi M}} \left(\kappa - \frac{\alpha_{\pi F}}{\alpha_{\pi M}} \right) \right) + \left(\frac{\kappa(\kappa+1)}{\alpha_{\pi M}} \right) \left(\frac{\kappa+1}{\alpha_{\pi F}} - \frac{1}{\alpha_{\pi M}} \right) > 0. \quad (5.2)$$

This condition is certainly met if policymakers' preferences coincide with those of society. An independent central bank may lead to lower debt accumulation only if it is less conservative than a dependent central bank sharing the government's preferences (in particular if $\alpha_{\pi M} < \alpha_{\pi F}/(\kappa+1)$). In this peculiar case, the government reduces debt to make up for the lack of conservatism of the independent central bank.

Inflation

In a static model, a more conservative central bank unambiguously enhances price stability. In a dynamic model, the effects on long-term price stability are less clear because a more conservative central bank may lead to more debt accumulation, thereby increasing inflationary pressures in the long run. Indeed, an increase in $\alpha_{\pi M}$ (for given $\alpha_{\pi F} > 0$) produces not only an intratemporal shift away from inflation towards higher taxes and lower public spending (as in the static model) but also an intertemporal shift in financing requirement. In particular, if $\alpha_{\pi M}$ is not too high, an increase in $\alpha_{\pi M}$ reduces β_{ND}^* , thereby shifting distortionary losses towards the second period and thus putting upward pressure on second-period inflation. Appendix F finds that the intertemporal effect dominates the intratemporal effect, and, hence, results in a higher second-period inflation only for small values of $\alpha_{\pi M}$. Accordingly, as an instrument to establish long-term price stability, a more conservative central bank is effective only if it is made conservative enough. Intuitively, if the central bank attaches a very high weight to price stability, the fiscal authority does not engage in the strategic accumulation of debt because it realises that the conservative central bank will barely raise second-period inflation in response to a higher second-period financing requirement.²¹

The result that, for relatively low values of $\alpha_{\pi M}$, a more conservative central bank may raise long-run inflation is reminiscent of the well known unpleasant monetarist arithmetic (see Sargent and Wallace, 1981), which implies that a tighter short-run monetary policy may lead to higher

²⁰ The result that a more conservative central bank raises debt accumulation appears in other places in the literature (see, e.g., Tabellini, 1986).

²¹ Indeed, for high values of $\alpha_{\pi M}$, a further increase in $\alpha_{\pi M}$ raises β_{ND}^* , thereby increasing asset accumulation and thus reinforcing the downward pressure of the intratemporal effect of an increase in $\alpha_{\pi M}$ on second-period inflation. Appendix F establishes that second-period inflation is increasing in $\alpha_{\pi M}$ for $\alpha_{\pi M} < \alpha_{\pi M}^*$, decreasing in $\alpha_{\pi M}$ for $\alpha_{\pi M} > \alpha_{\pi M}^*$ and, hence, reaches a global maximum if $\alpha_{\pi M} = \alpha_{\pi M}^*$, where $\alpha_{\pi M}^* \equiv \{[\beta_S^*(1+\rho)\alpha_{\pi F}]/[(1+\beta_S^*(1+\rho))(1/v^2 + 1/\alpha_{gS})]\}^{1/2}$.

inflation in the longer run. In contrast to Sargent and Wallace (1981), we derive this result as the time-consistent outcome of an explicitly formulated game between the fiscal and monetary authorities.

To explore this issue further, we compare the inflation performance under decentralized discretion with that under centralized commitment (see Section 3) under the assumptions that the policymakers share society's inflation aversion (i.e. $\alpha_{\pi M} = \alpha_{\pi F} = \alpha_{\pi S}$) and that $\kappa < 1$, which seems realistic for modern economies with efficient means of payment and hence low base money holdings. Under these assumptions, inflation is excessive under decentralized discretion (i.e. it exceeds the second-best level) in the static version of the model. As a direct consequence, the government strategically accumulates assets to reduce inflation in the second period. The associated shift in the financing requirement away from the second period may reverse the result from the static model that inflation is lowest under centralized commitment. In particular, second-period inflation is highest under centralized commitment if (see Appendix G)

$$\left(\frac{\beta_F^*(1+\rho)}{\beta_F^*(1+\rho)+1} \right) \left(\frac{\kappa}{\alpha_{\pi S}(1/v^2+1/\alpha_{gS})} \right) > 1. \quad (5.3)$$

This inequality is met if the following conditions are met. First, the government should be patient, so that a large part of the intertemporal financing requirement must be met in first period. Accordingly, a small shift in financing requirements exerts a major impact on the second-period inflation rate. The second condition is that the Phillips curve be steep, so that the strategic asset accumulation is indeed effective in inducing the central bank to raise the second-period inflation rate. Finally, inflation should account for a relatively large share of the financing requirement so that a lower second-period financing requirement implies a substantial drop in inflation at that time. Small inflation aversion, a large preference weight for public spending, and large money holdings contribute to such a relatively large share of seigniorage. In this connection, inequality (5.3) suggests that higher second-period inflation under centralized commitment (i.e. unpleasant monetarist arithmetic) is unlikely to occur in modern economies with small money holdings.

Welfare

To interpret the welfare losses contained in Table 2, we continue to assume that the policymakers share society's inflation aversion (i.e. $\alpha_{\pi M} = \alpha_{\pi F} = \alpha_{\pi S}$) and that $\kappa < 1$. Accordingly, inflation is excessive not only under centralized discretion (see Section 4) but also under decentralized discretion. The reason is that the distortion due to discretion (i.e. the self-defeating incentive facing discretionary monetary policymakers to boost output through unanticipated inflation) dominates the distortion due to decentralization (i.e. an independent central bank ignoring the beneficial social role of inflation in generating additional seigniorage revenues (which depends on κ)).

Accordingly, just as under centralized discretion (see Section 4), the inability to commit

under decentralized discretion results in two sources of additional welfare loss compared to the second best. The first source, the suboptimal *intra*temporal allocation of distortionary losses, stems from inflation being too high compared to the socially optimal inflation rate. The second source, the suboptimal *inter*temporal allocation of distortions, originates in the strategic use of the debt instrument. However, if the fiscal authority is myopic, the strategic effect (which reduces debt accumulation) offsets political distortions (which raise debt accumulation).

Optimal institutions

Letting the preferences of discretionary policymakers depart from societies' preferences may enhance welfare by offsetting the distortions associated with discretionary policymaking (see Rogoff, 1985). In particular, in the absence of political distortions (so that the government shares society's preferences), a *necessary* and *sufficient* condition for establishing the second best is that the price stability weight of the independent central bank is set according to ²²

$$\alpha_{\pi M} = \alpha_{\pi M}^{\text{opt}} \equiv \alpha_{\pi S}/\kappa. \quad (5.4)$$

An optimally designed independent central bank thus results in an optimal allocation of distortions not only intra- but also intertemporally. Intuitively, the incentive facing the first-period fiscal authority to use debt policy strategically originates in the inability to commit monetary policy in the second period. If this problem is removed by properly adjusting the preferences of the central bank, the fiscal authority no longer perceives any need to employ debt policy strategically in order to move second-period monetary policy closer to the social optimum.²³ Indeed, correcting monetary policy preferences is a direct way to eliminate the distortions due to the inability to commit.

Decentralized decisionmaking with an independent central bank facilitates optimal institutional design. In particular, with an independent central bank, the preferences of the government do not need to diverge from society's preferences. With centralized discretionary policymaking (i.e. a dependent central bank), in contrast, the government should not only be more impatient and conservative than society but also should even be more conservative than the optimally designed independent central bank (see Section 4, in particular, compare (5.4) with (4.5)).

The presence of political distortions complicates the optimal institutional design. In this case, granting an independent central bank the proper degree of conservatism (i.e. setting $\alpha_{\pi M}$ according to (5.4)) is no longer sufficient for attaining the second-best. Intuitively, changing monetary institutions is not the most appropriate instrument to deal with imperfect fiscal institutions. Indeed, with political distortions involving the preferences of the fiscal authorities in

²² This expression for the optimal degree of conservatism of an independent central bank coincides with the corresponding expression in the static model.

²³ The price stability weight of the central bank set according to (5.4) ensures that the effective discount rate β_{ND}^* equals the corresponding rate of society β_S^* .

addition to distortions due to the inability to commit monetary policy, the second best can be established only by employing two instruments, each targetted at one of the distortions. In particular, the second best is established by, first, properly designing monetary institutions to address the distortions due to discretionary policymaking (i.e. setting $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$) and, second, imposing an optimal debt target (given by (3.9))²⁴ to address the political distortions. This explains why the Delors Report (1989) on the design of monetary and fiscal institutions in the EMU emphasises the importance of debt ceilings as complements to a conservative, independent central bank.

To further explore the significance of debt ceilings, we investigate what happens if only monetary institutions can be designed optimally.²⁵ In that case, the second best can not be attained. Moreover, monetary institutions can no longer be targetted only at ensuring the optimal inflation rate, because they have to bear also the burden of dealing with political distortions. Indeed, eliminating the inflationary bias of discretionary policymaking by properly adjusting the price stability weight of the central bank worsens fiscal distortions due to myopic fiscal policymakers.

To explore these complications in more detail, we first consider the case where the government shares society's inflation aversion, but is myopic ($\beta_F < \beta_S$). In that case, the optimal price stability weight of the central bank, $\alpha_{\pi M}^{\text{opt}}$, trades off inter- and intratemporal distortions and lies between the weight $\alpha_{\pi M}^E$ ($0 < \alpha_{\pi M}^E < \alpha_{\pi S}/\kappa$) that minimizes the intertemporal loss factor and the weight $\alpha_{\pi S}/\kappa$ that minimizes the intratemporal loss factor (see Appendix H1). Accordingly, the central bank should be made less conservative than in the case of a benevolent fiscal authority in order to encourage the myopic fiscal authority to restrain debt accumulation so as to enhance the credibility of monetary policy. In this way, the need to alleviate political distortions distracts monetary policy from its primary mission of ensuring price stability. This explains why central bankers are strong advocates of instruments dealing more directly with fiscal myopia, such as ceilings on fiscal debt in the context of the EMU.

We now turn to the case of a fiscal authority who shares society's time preference rate but who is opportunistic (i.e. $\alpha_{\pi F} < \alpha_{\pi S}$).²⁶ In that case, whereas monetary distortions are eliminated (i.e. intratemporal losses are minimized) if $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$, fiscal distortions are taken away (i.e. intertemporal losses are minimized) if $\alpha_{\pi M} = \alpha_{\pi F}/\kappa$. The optimal degree of central bank conservatism trades off additional intra- and intertemporal losses. Whereas $\alpha_{\pi M}^{\text{opt}} > \alpha_{\pi F}/\kappa$, it cannot be ruled out that $\alpha_{\pi M}^{\text{opt}} > \alpha_{\pi S}/\kappa$ (see Appendix H2). This can be illustrated with the special case where the fiscal

²⁴ The optimal debt target puts a limit on debt accumulation or asset accumulation, depending on whether $\alpha_{\pi F}/\alpha_{\pi M} < \kappa$ or $\alpha_{\pi F}/\alpha_{\pi M} > \kappa$ (if $\beta_F = \beta_S$), or whether $\beta_F < \beta_S$ or $\beta_F > \beta_S$ (if $\alpha_{\pi F}/\alpha_{\pi M} = \kappa$).

²⁵ Indeed, compared to monetary institutions, fiscal institutions are much closer to the day-to-day political process. Hence, in practice, it may be impossible to deal with political distortions by imposing debt ceilings or by correcting the preferences of the government.

²⁶ Recall that in a static model the price stability weight of the government does not affect the equilibrium. Hence, in a static context the second best can be attained by setting the price stability weight of the independent central bank according to (5.4).

authority does not care at all about inflation, i.e. $\alpha_{\pi F}=0$. In that case, β_{ND}^* is monotonically increasing in $\alpha_{\pi M}$, but never exceeds β_S^* (at which value for β_D^* the intertemporal component of welfare losses is minimal). Accordingly, whereas increasing the price stability weight of the central bank from $\alpha_{\pi M}^{opt}=\alpha_{\pi S}/\kappa$ does not produce any first-order effects on the intratemporal component of the welfare loss, it still yields first-order reductions in the intertemporal component of the welfare loss. This implies that $\alpha_{\pi M}^{opt}>\alpha_{\pi S}/\kappa$. Intuitively, the central bank needs to be made more conservative than in the second best in order to act as a counterweight against the extremely opportunistic fiscal authority.

6. Conclusions

This paper investigated how the strategic interaction between monetary and fiscal authorities impacts debt policy. If a centralized, benevolent policymaker sets all policy instruments, the inability to commit produces welfare losses that are due not only to the usual intratemporal inflation bias but also to excessive accumulation of assets. With monetary policy decentralized to an independent central bank, the conflict between this central bank and the government about future monetary policy induces the government to use debt strategically. In the absence of political distortions, a properly designed conservative, independent central bank is sufficient to establish the second best. With an opportunistic or myopic government, however, these monetary institutions need to be supplemented by an optimal debt target in order to attain the second best. If myopia in fiscal policy cannot be corrected by a debt target, a conservative central bank may be counterproductive in that it leads to excessive debt accumulation. This provides a rationale for the public debt criterion in the Maastricht Treaty as a supplement to an independent European Central Bank, which gives priority to price stability.

Table 1: Policy outcomes under various regimes

Policy variable:	first period (r=C,D,ND)		second period (r=C,D,ND)	
$\kappa \pi_t$	$\omega_{\pi r} \beta_r^* \delta_r F$		$\omega_{\pi r} \delta_r F$	
$\tau_t + \tilde{x}_t/v$	$\omega_{\tau r} \beta_r^* \delta_r F$		$\omega_{\tau r} \delta_r F$	
$\tilde{g}_t - g_t$	$\omega_{gr} \beta_r^* \delta_r F$		$\omega_{gr} \delta_r F$	
d_1	$\frac{\tilde{K}_1 + (1+\rho)d_0 - \tilde{K}_2 + (1-\beta_r^*)\tilde{K}_2}{\beta_r^*(1+\rho)+1}$		N.A.	
Regime (r)	$\omega_{\pi r}$	$\omega_{\tau r}$	ω_{gr}	β_r^*
C	$\frac{\kappa^2/\alpha_{\pi F}}{P}$	$\frac{1/v^2}{P}$	$\frac{1/\alpha_{gS}}{P}$	$\beta_C^* \equiv \beta_F^*$
D	$\frac{\kappa(\kappa+1)/\alpha_{\pi F}}{D}$	$\frac{1/v^2}{D}$	$\frac{1/\alpha_{gS}}{D}$	$\beta_D^* \equiv \beta_F^* D^*/D$
ND	$\frac{\kappa/\alpha_{\pi M}}{N_D}$	$\frac{1/v^2}{N_D}$	$\frac{1/\alpha_{gS}}{N_D}$	$\beta_{ND}^* \equiv \beta_F^* N_D^*/N_D$

Note: 1. Subscript r (= C, D or ND) indicates the policy regime: C = centralized commitment, D = centralized discretion, ND = Nash discretion.

2. N.A. = not applicable.

3. Note that $\omega_{\pi r} + \omega_{\tau r} + \omega_{gr} = 1$, for r = C, D or ND.

4. $\beta_F^* \equiv \beta_F(1+\rho)$, $F \equiv K_1 + (1+\rho)d_0 + K_2/(1+\rho)$, $K_t \equiv \tilde{g}_t + \tilde{x}_t/v$,

$\delta_r \equiv (1+\rho)/[\beta_r^*(1+\rho)+1]$, $P \equiv \kappa^2/\alpha_{\pi F} + 1/v^2 + 1/\alpha_{gS}$, $D \equiv \kappa(\kappa+1)/\alpha_{\pi F} + 1/v^2 + 1/\alpha_{gS}$,

$D^* \equiv (\kappa+1)^2/\alpha_{\pi F} + 1/v^2 + 1/\alpha_{gS}$, $N_D \equiv \kappa/\alpha_{\pi M} + 1/v^2 + 1/\alpha_{gS}$,

$N_D^* \equiv \alpha_{\pi F}/\alpha_{\pi M}^2 + 1/v^2 + 1/\alpha_{gS}$.

Table 2: Welfare losses under various regimes

Policy regime:	welfare loss:	optimal preferences:
C	$\left(\frac{\frac{\kappa^2 \alpha_{\pi S}}{\alpha_{\pi F}^2} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{2P^2} \right) [\delta_C^2 ((\beta_F^*)^2 + \beta_S)] \tilde{F}^2$	$\beta_F = \beta_S, \alpha_{\pi F} = \alpha_{\pi S}$
D	$\left(\frac{\frac{(\kappa+1)^2 \alpha_{\pi S}}{\alpha_{\pi F}^2} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{2D^2} \right) [\delta_D^2 ((\beta_D^*)^2 + \beta_S)] \tilde{F}^2$	$\alpha_{\pi F} = \alpha_{\pi S}(\kappa+1)/\kappa,$ $\beta_F = \beta_S \left(\frac{\frac{\kappa^2}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{\frac{\kappa(\kappa+1)}{\alpha_{\pi S}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}} \right)$
ND	$\left(\frac{\frac{\alpha_{\pi S}}{\alpha_{\pi M}^2} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{2N_D^2} \right) [\delta_{ND}^2 ((\beta_{ND}^*)^2 + \beta_S)] \tilde{F}^2$	$\beta_F = \beta_S, \alpha_{\pi M} = \alpha_{\pi S}/\kappa$

Note: For definitions, see Table 1.

Technical appendices

A: Derivation of equilibrium policies under centralized commitment.

The equilibrium is derived by working back in time and solving for the optimal policies given the current value of the state variable (public debt) and given that future policies are optimally selected.

Substitute (2.1) into (2.3) (for $t=2$) and impose $\pi_2^e = \pi_2$, so that the second-period Lagrangian of the fiscal authority can be written as,

$$\mathcal{L} = \frac{1}{2}[\alpha_{\pi F}\pi_2^2 + (v\tau_2 + \tilde{x}_2)^2 + \alpha_{gS}(g_2 - \tilde{g}_2)^2] + \lambda_2[g_2 + (1+\rho)d_1 - \tau_2 - \kappa\pi_2], \quad (\text{A.1})$$

where λ_2 is the Lagrange multiplier associated with the government budget constraint in the second period. The first order conditions (given the linear-quadratic specification of the problem, the first order conditions are necessary and sufficient for the optimum) for π_2 , τ_2 and g_2 are given by, respectively,

$$\alpha_{\pi F}\pi_2 = \lambda_2\kappa, \quad (\text{A.2})$$

$$v(v\tau_2 + \tilde{x}_2) = \lambda_2, \quad (\text{A.3})$$

$$\alpha_{gS}(\tilde{g}_2 - g_2) = \lambda_2, \quad (\text{A.4})$$

Eliminate λ_2 from the system (A.2)-(A.4) to obtain:

$$\pi_2 = (\kappa^2 v^2 / \alpha_{\pi F})(\tau_2 + \tilde{x}_2 / v), \quad (\text{A.5})$$

$$\tilde{g}_2 - g_2 = (v^2 / \alpha_{gS})(\tau_2 + \tilde{x}_2 / v), \quad (\text{A.6})$$

Combine (A.5) and (A.6) with the government financing requirement (2.7) for period 2, to obtain the second-period policy outcomes for given value of d_1 :

$$\pi_2 = \left(\frac{\kappa / \alpha_{\pi F}}{P} \right) (\tilde{K}_2 + (1+\rho)d_1), \quad (\text{A.7})$$

$$\tau_2 + \tilde{x}_2 / v = \left(\frac{1 / v^2}{P} \right) (\tilde{K}_2 + (1+\rho)d_1), \quad (\text{A.8})$$

$$\tilde{g}_2 - g_2 = \left(\frac{1 / \alpha_{gS}}{P} \right) (\tilde{K}_2 + (1+\rho)d_1), \quad (\text{A.9})$$

where $P \equiv \kappa^2 / \alpha_{\pi F} + 1 / v^2 + 1 / \alpha_{gS}$. Substitution of (A.1)-(A.3) into the fiscal authority's welfare loss function (and imposing $\pi_2^e = \pi_2$), yields a second period welfare loss of $\frac{1}{2}P^{-1}[\tilde{K}_2 + (1+\rho)d_1]^2$.

Therefore, if we substitute (2.1) into (2.3) (for $t=1$) and impose $\pi_1^e = \pi_1$, the first-period Lagrangian of the fiscal authority can be written as,

$$\mathcal{L} = \frac{1}{2}[\alpha_{\pi F}\pi_1^2 + (v\tau_1 + \tilde{x}_1)^2 + \alpha_{gS}(g_1 - \tilde{g}_1)^2] + \frac{1}{2}\beta_F P^{-1}[\tilde{K}_2 + (1+\rho)d_1]^2 +$$

$$\lambda_1 [g_1 + (1+\rho)d_0 - \tau_1 - \kappa\pi_1 - d_1], \quad (\text{A.10})$$

where λ_1 is the Lagrange multiplier associated with the government budget constraint in the first period. The first order conditions for π_1 , τ_1 , g_1 and d_1 are given by, respectively,

$$\alpha_{\pi F} \pi_1 = \lambda_1 \kappa, \quad (\text{A.11})$$

$$v(v\tau_1 + \tilde{x}_1) = \lambda_1, \quad (\text{A.12})$$

$$\alpha_{gS}(\tilde{g}_1 - g_1) = \lambda_1, \quad (\text{A.13})$$

$$\beta_F P^{-1} [K_2 + (1+\rho)d_1] (1+\rho) = \lambda_1. \quad (\text{A.14})$$

Combine (A.11)-(A.13) with the government financing requirement (2.7) for period 1, to yield

$$v(v\tau_1 + \tilde{x}_1) = P^{-1} [K_1 + (1+\rho)d_0 - d_1]. \quad (\text{A.15})$$

Combine (A.12), (A.14) and (A.15) to give

$$[K_1 + (1+\rho)d_0 - d_1] = \beta_F (1+\rho) [K_2 + (1+\rho)d_1]. \quad (\text{A.16})$$

Equation (A.16) can be rewritten as,

$$d_1 = [\beta_F^* (1+\rho) + 1]^{-1} \{ [K_1 + (1+\rho)d_0 - K_2] + (1 - \beta_F^*) K_2 \}, \text{ where } \beta_F^* \equiv \beta_F (1+\rho). \quad (\text{A.17})$$

Substitute (A.17) into (A.15) and rewrite to give the equilibrium tax rate in period 1,

$$\tau_1 + \tilde{x}_1 / v = \left(\frac{1/v^2}{P} \right) \left(\frac{\beta_F^* (1+\rho) (\tilde{K}_1 + (1+\rho)d_0) + \beta_F^* \tilde{K}_2}{\beta_F^* (1+\rho) + 1} \right). \quad (\text{A.18})$$

Similarly, substitute (A.17) into (A.8) and rewrite to give the equilibrium tax rate in period 2,

$$\tau_2 + \tilde{x}_2 / v = \left(\frac{1/v^2}{P} \right) \left(\frac{(1+\rho) (\tilde{K}_1 + (1+\rho)d_0) + \tilde{K}_2}{\beta_F^* (1+\rho) + 1} \right). \quad (\text{A.19})$$

It can be easily verified that (A.18) and (A.19) coincide with the corresponding "compressed" expressions presented in Table 1. The expressions for the other policy variables can be found in a similar way using the first-order conditions for the policy instruments in the first and the second period.

B: Proof of (4.2), the condition under which second period inflation is lower with centralized discretion than with centralized commitment.

Using Table 1 and the assumption that the authorities' price stability weights coincide with society's, we find that second-period inflation is lower with centralized discretion than with centralized commitment if and only if,

$$\begin{aligned}
& \left(\frac{\kappa/\alpha_{\pi S}}{P} \right) \left(\frac{(1+\rho)\tilde{F}}{\beta_F^*(1+\rho)+1} \right) > \left(\frac{(\kappa+1)/\alpha_{\pi S}}{D} \right) \left(\frac{(1+\rho)\tilde{F}}{\beta_F^*(D^*/D)(1+\rho)+1} \right) \Leftrightarrow \\
& \beta_F^*(1+\rho)(\kappa D^* - (\kappa+1)P) + (\kappa D - (\kappa+1)P) > 0 \Leftrightarrow \\
& \beta_F^*(1+\rho) \left(\frac{\kappa(\kappa+1)}{\alpha_{\pi S}} - \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \right) - \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) > 0 \Leftrightarrow \\
& \beta_F^*(1+\rho) \left(\frac{\kappa(\kappa+1)}{\alpha_{\pi S}} \right) > \left(\beta_F^*(1+\rho)+1 \right) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right). \tag{B.1}
\end{aligned}$$

Divide both sides by the right hand side of (B.1) to yield (4.2).

C: Derivation optimal debt target under centralized discretion.

The optimal debt target follows immediately from the minimisation (over $\hat{d}_1$) of

$$\left(\frac{(\kappa+1)^2 \alpha_{\pi S} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{\frac{\alpha_{\pi F}^2}{2D^2}} \right) \left(\left(\tilde{K}_1 + (1+\rho)d_0 - \hat{d}_1 \right)^2 + \beta_S \left(\tilde{K}_2 + (1+\rho)\hat{d}_1 \right)^2 \right).$$

D: Derivation of the equilibrium policies under decentralized discretion.

The central bank and the fiscal authority play a Nash game in the first and second period. The central bank chooses the inflation rate taking as given the fiscal authority's policy choices and taking as given the expected inflation rate. The fiscal authority selects the τ_2 and g_2 in period 2, taking as given π_2^e and π_1^e , and τ_1 , g_1 and d_1 in period 1, taking as given π_1 and π_1^e .

In period 2 the central bank selects π_2 to minimize the expression $\frac{1}{2}[\alpha_{\pi M}\pi_2^2 + (v(\pi_2 - \pi_2^e - \tau_2) - \tilde{x}_2)^2 + \alpha_{gS}(g_2 - \tilde{g}_2)^2]$. The first-order condition yields the central bank's reaction function,

$$\pi_2 = v^2(\alpha_{\pi M} + v^2)^{-1} (\pi_2^e + \tau_2 + \tilde{x}_2). \tag{D.1}$$

The second period Lagrangian of the fiscal authority is,

$$\mathcal{L} = \frac{1}{2}[\alpha_{\pi F}\pi_2^2 + (v(\pi_2 - \pi_2^e - \tau_2) - \tilde{x}_2)^2 + \alpha_{gS}(g_2 - \tilde{g}_2)^2] + \lambda_2[g_2 + (1+\rho)d_1 - \tau_2 - \kappa\pi_2], \tag{D.2}$$

where λ_2 is the Lagrange multiplier associated with the government budget constraint in period 2. The first order conditions for τ_2 and g_2 are, respectively,

$$-v(v(\pi_2 - \pi_2^e - \tau_2) - \tilde{x}_2) = \lambda_2, \tag{D.3}$$

$$\alpha_{gs}(\tilde{g}_2 - g_2) = \lambda_2, \quad (D.4)$$

Impose rationality of expectations $\pi_2^e = \pi_2$ upon (D.1) and (D.3) and combine the resulting expressions and (D.4) with the government financing requirement (2.7) for period 2, to yield

$$v(v\tau_2 + \tilde{x}_2) = N_D^{-1}[K_2 + (1+\rho)d_2], \quad (D.5)$$

where $N_D = \kappa/\alpha_{\pi M} + 1/v^2 + 1/\alpha_{gs}$. Hence, using (D.1) ($\pi_2^e = \pi_2$), (D.3) and (D.4), we arrive at,

$$\pi_2 = \left(\frac{1/\alpha_{\pi M}}{N_D} \right) (\tilde{K}_2 + (1+\rho)d_1), \quad (D.6)$$

$$\tau_2 + \tilde{x}_2/v = \left(\frac{1/v^2}{N_D} \right) (\tilde{K}_2 + (1+\rho)d_1), \quad (D.7)$$

$$\tilde{g}_2 - g_2 = \left(\frac{1/\alpha_{gs}}{N_D} \right) (\tilde{K}_2 + (1+\rho)d_1), \quad (D.8)$$

Substitution of (D.6)-(D.8) into the fiscal authority's welfare loss function yields a second period welfare loss of $\frac{1}{2}(N_D^*/N_D^2)[K_2 + (1+\rho)d_1]^2$, where $N_D^* = \alpha_{\pi F}/\alpha_{\pi M}^2 + 1/v^2 + 1/\alpha_{gs}$.

In the first period, the central bank selects π_1 to minimize the expression $\frac{1}{2}[\alpha_{\pi M}(\pi_1 - \pi_1^e)^2 + (v(\pi_1 - \pi_1^e - \tau_1) - \tilde{x}_1)^2 + \alpha_{gs}(g_1 - \tilde{g}_1)^2]$. The first-order condition yields the central bank's reaction function,

$$\pi_1 = v^2(\alpha_{\pi M} + v^2)^{-1} (\pi_1^e + \tau_1 + \tilde{x}_1). \quad (D.9)$$

The first-period Lagrangian of the fiscal authority is,

$$\begin{aligned} \mathcal{L} = & \frac{1}{2}[\alpha_{\pi F}\pi_1^2 + (v(\pi_1 - \pi_1^e - \tau_1) - \tilde{x}_1)^2 + \alpha_{gs}(g_1 - \tilde{g}_1)^2] + \frac{1}{2}\beta_F(N_D^*/N_D^2)[K_2 + (1+\rho)d_1]^2 + \\ & \lambda_1[g_1 + (1+\rho)d_0 - \tau_1 - \kappa\pi_1 - d_1], \end{aligned} \quad (D.10)$$

where λ_1 is the Lagrange multiplier associated with the government budget constraint in period 1. The first order conditions for τ_1 , g_1 and d_1 are given by, respectively,

$$-v(v(\pi_1 - \pi_1^e - \tau_1) - \tilde{x}_1) = \lambda_1, \quad (D.11)$$

$$\alpha_{gs}(\tilde{g}_1 - g_1) = \lambda_1, \quad (D.12)$$

$$\beta_F(N_D^*/N_D^2)[K_2 + (1+\rho)d_1](1+\rho) = \lambda_1. \quad (D.13)$$

Impose rationality of expectations $\pi_1^e = \pi_1$ upon (D.9) and (D.11) and combine the resulting expressions and (D.12) with the government financing requirement (2.7) for period 1, to yield

$$v(v\tau_1 + \tilde{x}_1) = N_D^{-1}[K_1 + (1+\rho)d_0 - d_1]. \quad (D.14)$$

Impose rational expectations ($\pi_1^e = \pi_1$) on (D.11) and substitute (D.14) into the resulting expression for (D.11) to yield $N_D^{-1}[K_1 + (1+\rho)d_0 - d_1] = \lambda_1$. This can be substituted into (D.13) to give

$$[K_1 + (1+\rho)d_0 - d_1] = \beta_F^*(1+\rho)(N_D^*/N_D)[K_2 + (1+\rho)d_1], \quad (D.15)$$

Equation (D.15) can be rewritten as,

$$d_1 = [\beta_{ND}^*(1+\rho)+1]^{-1} \{ [K_1 + (1+\rho)d_0 - K_2] + (1-\beta_{ND}^*)K_2 \}, \text{ where } \beta_{ND}^* \equiv \beta_F^*(N_D^*/N_D). \quad (D.16)$$

Substitute (D.16) into (D.14) and rewrite to give the equilibrium tax rate in period 1,

$$\tau_1 + \tilde{x}_1/v = \left(\frac{1/v^2}{N_D} \right) \left(\frac{\beta_{ND}^*(1+\rho)(\tilde{K}_1 + (1+\rho)d_0) + \beta_{ND}^* \tilde{K}_2}{\beta_{ND}^*(1+\rho)+1} \right). \quad (D.17)$$

Similarly, substitute (D.16) into (D.7) and rewrite to give,

$$\tau_2 + \tilde{x}_2/v = \left(\frac{1/v^2}{N_D} \right) \left(\frac{(1+\rho)(\tilde{K}_1 + (1+\rho)d_0) + \tilde{K}_2}{\beta_{ND}^*(1+\rho)+1} \right). \quad (D.18)$$

It can be easily verified that (D.17) and (D.18) coincide with the corresponding "compressed" expressions presented in Table 1. The expressions for the other policy variables can be found in a similar way using the first-order conditions and the central bank's reaction functions in the first and second period.

E: Proof of (5.2), the condition under which centralized discretion leads to less debt accumulation than decentralized discretion.

Note that debt accumulation is decreasing in the "effective discount factor", i.e. in β_D^* in the case of centralized discretion and in β_{ND}^* in the case of decentralized discretion. Hence, centralized discretion leads to less debt accumulation than decentralized discretion if and only if $D^*/D > N_D^*/N_D$. This is equivalent to

$$\left(\frac{(\kappa+1)^2}{\alpha_{\pi F}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \left(\frac{\kappa}{\alpha_{\pi M}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) > \left(\frac{\kappa(\kappa+1)}{\alpha_{\pi F}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \left(\frac{\alpha_{\pi F}}{\alpha_{\pi M}^2} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right).$$

Working out the products (treating $(1/v^2 + 1/\alpha_{gS})$ as a single term), cancelling the term $(1/v^2 + 1/\alpha_{gS}^2)$ on both sides, bringing all terms on the right hand side to the left hand side and rearranging yields (5.2):

$$\left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \left(\frac{(\kappa+1)}{\alpha_{\pi F}} + \frac{1}{\alpha_{\pi M}} \left(\kappa - \frac{\alpha_{\pi F}}{\alpha_{\pi M}} \right) \right) + \left(\frac{\kappa(\kappa+1)}{\alpha_{\pi M}} \right) \left(\frac{\kappa+1}{\alpha_{\pi F}} - \frac{1}{\alpha_{\pi M}} \right) > 0.$$

Note that both terms on the left hand side equal zero if $\alpha_{\pi M} = \alpha_{\pi F}/(\kappa+1)$ and are negative if $0 < \alpha_{\pi M} < \alpha_{\pi F}/(\kappa+1)$.

F: Behavior of second-period inflation as function of $\alpha_{\pi M}$ for given $\alpha_{\pi F}$.

Second-period inflation can be written as,

$$\pi_2 = \left(\frac{1/\alpha_{\pi M}}{\beta_S^*(1+\rho)N_D^* + N_D} \right) \left((1+\rho)(\tilde{K}_1 + (1+\rho)d_0) + \tilde{K}_2 \right).$$

Differentiate the first factor between brackets with respect to $\alpha_{\pi M}$, to yield,

$$\frac{-\left(\frac{1}{\alpha_{\pi M}^2} \right) \left(1 + \beta_S^*(1+\rho) \right) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) + \beta_S^*(1+\rho) \left(\frac{\alpha_{\pi F}}{\alpha_{\pi M}^4} \right)}{\left(\beta_S^*(1+\rho) \left(\frac{\alpha_{\pi F}}{\alpha_{\pi M}^2} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) + \left(\frac{\kappa}{\alpha_{\pi M}} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \right)^2}. \quad (F.1)$$

Expression (F.1) is positive for $0 \leq \alpha_{\pi M} < \{ [\beta_S^*(1+\rho)\alpha_{\pi F}] / [(1+\beta_S^*(1+\rho))(1/v^2 + 1/\alpha_{gS})] \}^{1/2}$ and negative for $\alpha_{\pi M} > \{ [\beta_S^*(1+\rho)\alpha_{\pi F}] / [(1+\beta_S^*(1+\rho))(1/v^2 + 1/\alpha_{gS})] \}^{1/2}$. Hence, π_2 reaches a global maximum at $\alpha_{\pi M}^* = \alpha_{\pi M}^* \equiv \{ [\beta_S^*(1+\rho)\alpha_{\pi F}] / [(1+\beta_S^*(1+\rho))(1/v^2 + 1/\alpha_{gS})] \}^{1/2}$.

G: Proof of (5.3), the condition under which (for $\kappa < 1$) second period inflation is lower with decentralized discretion than with centralized commitment.

Assume that $\kappa < 1$. Using Table 1 and the assumption that the authorities' price stability weights coincide with society's, we find that second period inflation is lower with decentralized discretion than with centralized commitment if and only if,

$$\left(\frac{\kappa/\alpha_{\pi S}}{P} \right) \left(\frac{(1+\rho)\tilde{F}}{\beta_F^*(1+\rho)+1} \right) > \left(\frac{1/\alpha_{\pi S}}{N_D} \right) \left(\frac{(1+\rho)\tilde{F}}{\beta_F^*(N_D^*/N_D)(1+\rho)+1} \right) \Leftrightarrow$$

$$\beta_F^*(1+\rho)(P - \kappa N_D^*) + (P - \kappa N_D) < 0 \Leftrightarrow$$

$$\beta_F^*(1+\rho) \left(\frac{\kappa(\kappa-1)}{\alpha_{\pi S}} + (1-\kappa) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \right) + (1-\kappa) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) < 0.$$

Divide by $(\kappa-1)$ (< 0) to give,

$$\beta_F^*(1+\rho) \left(\frac{\kappa}{\alpha_{\pi S}} - \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) \right) - \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right) > 0 \Leftrightarrow$$

$$\beta_F^*(1+\rho) \left(\frac{\kappa}{\alpha_{\pi S}} \right) > (\beta_F^*(1+\rho)+1) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right). \quad (G.1)$$

Divide both sides by the right hand side of (G.1) to yield (5.3).

H: Optimal central bank weight in the presence of political distortions.

One can write society's welfare loss as

$$L_A L_E F^2, \quad (H.1)$$

where

$$L_A \equiv \left(\frac{\frac{\alpha_{\pi S}}{\alpha_{\pi M}^2} + \frac{1}{v^2} + \frac{1}{\alpha_{gS}}}{2N_D^2} \right) > 0, \quad (H.2)$$

$$L_E \equiv \left(\frac{(1+\rho)^2 (\beta_{ND}^*)^2 + \beta_S}{(\beta_{ND}^* (1+\rho) + 1)^2} \right) > 0. \quad (H.3)$$

Let us first establish some properties of L_A , the intratemporal component of the welfare loss, and L_E , the intertemporal component of the welfare loss.

Differentiate L_A with respect to $\alpha_{\pi M}$, to yield,

$$\frac{\partial L_A}{\partial \alpha_{\pi M}} = \left(\frac{\frac{1}{\alpha_{\pi M}^2} \left(\kappa - \frac{\alpha_{\pi S}}{\alpha_{\pi M}} \right) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right)}{N_D^3} \right). \quad (H.4)$$

Hence, L_A is decreasing (increasing) for $\alpha_{\pi M} < (>) \alpha_{\pi S}/\kappa$ so that it reaches its global minimum at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$.

Differentiate L_E with respect to $\alpha_{\pi M}$, to yield,

$$\frac{\partial L_E}{\partial \alpha_{\pi M}} = 2(1+\rho)^2 \left(\frac{\beta_{ND}^* - \beta_S}{(\beta_{ND}^* (1+\rho) + 1)^3} \right) \left(\frac{\partial \beta_{ND}^*}{\partial \alpha_{\pi M}} \right). \quad (H.5)$$

The first factor between square brackets on the right hand side of (H.5) is negative (positive) if $\beta_{ND}^* < (>) \beta_S^*$. Furthermore,

$$\frac{\partial \beta_{ND}^*}{\partial \alpha_{\pi M}} = \left(\frac{-\frac{\kappa \alpha_{\pi F}}{\alpha_{\pi M}^4} + \frac{1}{\alpha_{\pi M}^2} \left(\kappa - 2 \left(\frac{\alpha_{\pi F}}{\alpha_{\pi M}} \right) \right) \left(\frac{1}{v^2} + \frac{1}{\alpha_{gS}} \right)}{N_D^2} \right) \beta_F^*, \quad (H.6)$$

which is negative for values of $\alpha_{\pi M} \leq 2\alpha_{\pi F}/\kappa$.

*H1: Proof that $\alpha_{\pi M}^E < \alpha_{\pi M}^{opt} < \alpha_{\pi S}/\kappa$ if $\beta_F < \beta_S$ and $\alpha_{\pi F} = \alpha_{\pi S}$
(where $\alpha_{\pi M}^E > 0$ is defined as the value of $\alpha_{\pi M}$ which minimizes the intratemporal loss factor).*

The proof consists of the following steps, in which we show that: (i) L_E reaches its global minimum

at $\alpha_{\pi M} = \alpha_{\pi M}^E$, where $0 < \alpha_{\pi M}^E < \alpha_{\pi S}/\kappa$; (ii) L_A is decreasing for $\alpha_{\pi M} \leq \alpha_{\pi M}^E$ and L_E is decreasing for $\alpha_{\pi M} < \alpha_{\pi M}^E$, hence there exists a value of $\alpha_{\pi M} > \alpha_{\pi M}^E$, such that society's welfare loss is lower than for any $0 < \alpha_{\pi M} \leq \alpha_{\pi M}^E$; (iii) L_E , when evaluated at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$, is increasing and is lower than when evaluated at any other $\alpha_{\pi M} > \alpha_{\pi S}/\kappa$. Given that L_A reaches a global minimum for $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$ (the minimum is interior, hence the slope of L_A is flat at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$ and, hence, there are no first-order effects on L_A of a change in $\alpha_{\pi M}$ when evaluated at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$), it then follows that $\alpha_{\pi M}^E < \alpha_{\pi M}^{opt} < \alpha_{\pi S}/\kappa$.

Step (i): Remember that for $\alpha_{\pi M} \leq \alpha_{\pi F}/\kappa = \alpha_{\pi S}/\kappa$, β_{ND}^* is decreasing in $\alpha_{\pi M}$. At $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$, $\beta_{ND}^* = \beta_S^* < \beta_F^*$. Moreover, β_{ND}^* goes to infinity as $\alpha_{\pi M}$ approaches zero from above. Hence, by continuity, there is a (unique) value of $\alpha_{\pi M}$, denoted by $\alpha_{\pi M}^E$, between 0 and $\alpha_{\pi S}/\kappa$ at which $\beta_{ND}^* = \beta_E^*$. L reaches its global minimum at $\beta_{ND}^* = \beta_S^*$, hence at $\alpha_{\pi M} = \alpha_{\pi M}^E$.

Step (ii): Because $\alpha_{\pi M}^E < \alpha_{\pi S}/\kappa$, it follows immediately that L_A is decreasing for $\alpha_{\pi M} \leq \alpha_{\pi M}^E$. Moreover, we have seen that β_{ND}^* is decreasing for $\alpha_{\pi M} < \alpha_{\pi S}/\kappa = \alpha_{\pi S}/\kappa$, hence, by the definition of $\alpha_{\pi M}^E$, $\beta_{ND}^* > \beta_S^*$ for $\alpha_{\pi M} < \alpha_{\pi M}^E$. Hence, for $\alpha_{\pi M} < \alpha_{\pi M}^E$, $\partial L_E / \partial \beta_{ND}^* > 0$ and $\partial \beta_{ND}^* / \partial \alpha_{\pi M} < 0$, and, hence, $\partial L_E / \partial \alpha_{\pi M} < 0$.

Step (iii): Remember that at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$, $\beta_{ND}^* = \beta_F^* < \beta_S^*$, and, hence, $\partial L_E / \partial \beta_{ND}^* < 0$ at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$. Remember also that β_{ND}^* is decreasing at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$. Therefore, $\partial L_A / \partial \alpha_{\pi M} > 0$ at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$. Furthermore, $N_D/N = 1$ at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$, while $N_D^*/N_D < 1$ for $\alpha_{\pi M} > \alpha_{\pi S}/\kappa$, as is easy to check. Hence, for $\alpha_{\pi M} > \alpha_{\pi S}/\kappa$, $\beta_{ND}^* < \beta_F^* < \beta_S^*$. Because L_E is monotonically decreasing in β_{ND}^* for $\beta_{ND}^* < \beta_S^*$, L_E when evaluated at $\alpha_{\pi M} = \alpha_{\pi S}/\kappa$ (hence $\beta_{ND}^* = \beta_F^*$) must be lower than L_E , when evaluated at some $\alpha_{\pi M} > \alpha_{\pi S}/\kappa$.

H2: Proof that $\alpha_{\pi M}^{opt} > \alpha_{\pi F}/\kappa$ if $\alpha_{\pi F} < \alpha_{\pi S}$ and $\beta_F = \beta_S$.

Because $\alpha_{\pi F} < \alpha_{\pi S}$, $\beta_{ND}^* > \beta_F^* = \beta_S^*$ for $\alpha_{\pi M} \leq \alpha_{\pi F}/\kappa$. Also, because $\alpha_{\pi F} < \alpha_{\pi S}$, $\partial \beta_{ND}^* / \partial \alpha_{\pi M} < 0$ for $\alpha_{\pi M} \leq \alpha_{\pi F}/\kappa$. Hence, L_E is decreasing for $\alpha_{\pi M} \leq \alpha_{\pi F}/\kappa$. Finally, because $\alpha_{\pi F} < \alpha_{\pi S}$, L_A is decreasing for $\alpha_{\pi M} \leq \alpha_{\pi F}/\kappa$. Hence, L_A is decreasing for $\alpha_{\pi M} \leq \alpha_{\pi F}/\kappa$ and, hence, the optimal inflation weight of the central bank is greater than $\alpha_{\pi F}/\kappa$ (and potentially infinitely large).
