Publisher's PDF, also known as Version of record

Please check the document version of this publication:

• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

We have examined SER functioning (a) by measuring basal and stimulated concentrations of intraplatelet free calcium ([Ca^2+]), in response to thrombin (1 unit/ml), using fura-2 and (b) by measuring the specific activities of calcium dependent enzymes such as, Ca^2+/-ATPase, Mg2+/-ATPase and Ca^2+/-ATPase, using methods well known for measurement of inorganic phosphate. Our results (Table 1) show that there was a significant increase in the percentage of [Ca^2+] released above the basal levels with thrombin stimulation in AD platelets compared to controls. This was partly due to a lower basal and higher stimulated [Ca^2+] in AD platelets compared to controls. We have also found that the specific activities of Ca^2+/-ATPase and Mg2+/-ATPase of AD platelets were significantly reduced in AD platelets compared to controls (Table 1).

These data suggest that calcium homeostasis is altered in AD platelets. This is comparable to the findings in AD fibroblasts (3). An important question which may be raised is the CNS pathophysiology of this disorder.

434 DIFFERENT PATTERNS OF CSF MONOAMINE METABOLITES IN OLD-AGE DEMENTIAS. L. Parnetti, A. Galli, P. Menegazzi, D. Cadini, M. Brunetti, U. Seni. Chair: of Gerontology and Geriatrics; Chair of Biochemistry, Perugia University, 06100 Perugia, ITALY.

Many investigations have been carried out in recent years in an attempt to clarify the ethical pathognomonic role of neurotransmitter deficiencies in dementia disorders. With regard to "ex vivo" studies on bio-genic amines, which have importance in regulating cognitive and motor functions, attention has been focused on CSF levels of the key breakdown products of these neurotransmitters homovanillic acid - HVA- for dopamine, hydroxy-indoleacetic acid (5-HIAA) for serotonin and 3-methoxy-4-hydroxyphenyl-ethyl-glycol (MHPG) for norepinephrine, since they reflect the central neurochemical activity. The aim of this study was to better understanding the pathogenetic usefulness of these biological markers in dementia disorders, we have thus measured CSF levels of the main metabolites of monoamines (HVA, 5-HIAA and MHPG) in patients with early-onset Alzheimer's disease (e.-AD, n. 12), late-onset AD (1-AD, n. 13), vascular dementia (VD, n. 13), simple senile dementia (SSD, n. 9) and twelve elderly controls. Psychobehavioural assessment was also carried out by means of MMSE and GBS Rating Scale for Dementia. Mean HHF levels did not differ from controls among the groups considered, while 5-HIAA was slightly lower (0.10>p>0.05) in e-AD, 1-AD and VD; HVA was consistently decreased (p<0.02) in e-AD and 1-AD showing a slight reduction (0.10>p>0.05) in VD. No variation was found in SSD.

Negative and directly distributed correlations between neurochemical and psychobehavioural parameters were observed in 1-AD, VD and SSD groups, while no relationship between these variables was documented in e-AD. These results confirm that CSF levels of monoamine metabolites are of scarce diagnostic value but reinforce the evidence of the clinical heterogeneity of old-age dementias and the potential importance of these clinical-biological studies in view of differentiated therapeutic treatments.

444 VITAMIN, METALS AND ROUTINE BLOODCHEMISTRY IN NORMAL AGING: RESULTS FROM A MULTIPLE COHORT STUDY. N. Bohnen, J. Jolles and C. Depenarz. Dept of Neuropsychology & Psychology; Limburg University; Box 616; 6200 MD Maastricht; The Netherlands.

Up till now, there is a very limited number of studies in which parameters in normal aging; there are only few reports on a reasonably representative sample from the normal population who include young as well as old subjects. This restricts the possibilities to study pathogenic factors with respect to blood parameters in age related diseases such as Alzheimer's disease, because reference values from healthy control subjects are needed for that purpose. The present research project aims at, first, providing objective information on age-dependent changes in blood levels of vitamins, minerals and routine chemical parameters. The second objective was the establishment of objective norms for a comparison with AD and depression. The study was performed on 4 cohorts of healthy subjects who had undergone a rigorous health screening in order to exclude biasing factors such as iatrogenic factors for brain dysfunction and dysfunctions in the realm of internal medicine. The cohorts were 20 (±3), 60 (±5), 60 (±5) and 80 (±5) with 10 males and 10 females per cohort. Venous blood samples were collected after an overnight fast between 8.00 and 9.00 am. The parameters under investigation were: vitamins, minerals, hormones and routine blood chemistry. The effects of age and sex were evaluated for each variable by ANOVA. From the 19 routine parameters (Na, K, Cl, Ca, Ca-ion, F, Fe, Mg, plasmaosmolality, total protein, albumin, triglycerides, cholesterol, creatinin, creatinin, liver enzymes and alkaline phosphatase), 11 demonstrated significant abnormalities related to age and these included Ca, P, Albinum, Cholesterol, BUN, creatinin, liver enzymes and alkaline phosphatase. In addition there were sex related differences in aging (for example with neuropsychiatric and BUN) Further results in this disease-free population are that there is no evidence of a decline of blood vitamin levels (B1, B2, B12 and C) with aging. Furthermore, we have determined the potential for change in normal aging (such as zinc). The results with respect to trace metals, neurotoxic elements and hormones will be reported at a later occasion. The findings may have an important impact in that they provide norms for a well characterized healthy aging population. In addition, this population appears characterized by age related changes in several blood parameters without change in vitamins. Age related decreases in vitamins found in earlier studies may be the result of inclusion of non-healthy individuals in the sample.

435 CORRELATIONS BETWEEN AMONG PURINES AND PURINE METABOLITES IN ALZHEIMER'S DISEASE. P. E. Milbury, E.A. Ryan, M.F. Bear, W.R. Matson, JESA, Inc., Bedford, MA 01730 USA and Massachusetts General Hospital, Dept. of Neurology, Boston, MA 02114 USA.

Through the utilization of large, multiparameter data bases containing sufficiently reliable information, data which may seem chaotic can be used in the definition of normal metabolism and the altered state metabolism associated with specific disorders. Studies in Alzheimer's disease suggest that dietary levels of tryptophan and tyrosine profoundly affect the levels of various neurotransmitters. Deficiencies in purine metabolism have been linked to neurochemical lesion in Parkinson's Disease, while variations in purine metabolites have been implicated in Alzheimer type dementias.

A multiparameter data base has been created utilizing a Coulomb® Electrode Array System. Approximately 1000 Alzheimer, Huntington, Parkinson, control tissue and CSF samples comprise this data base. We have analyzed these data for potential metabolic interactions between the purine, pyrimidine, amines and tryptophan pathways. A strong correlation has been observed between levels of tyrosine and xanthine. Tyrosine/xanthine ratios were found to be significantly decreased in the putamen and A4 of the Parkinson samples. Guanosine levels in putamen, A20, A21, A9, and A4 in Alzheimer samples were decreased approximately 50 percent of control values. Alterations in the metabolism of purines and pyrimidines in Alzheimer type dementia might be important in the CNS pathophysiology of this disorder.
