This article studies the use and impact of a (‘Employability-miles’) voucher scheme. These vouchers could be used for participation in a restricted number of training courses, which all aim to stimulate employees to develop a more active attitude towards their own employability. Using data from two surveys of one firm’s workforce, we find that voucher use is related to various personality traits and personal characteristics. In particular, a worker’s ambition, goal setting and education level are positively related to voucher use. In addition, workers with longer tenure spend their vouchers more often. Conversely, workers with a more positive self-image as well as those who are negatively reciprocal spend their vouchers less often. The negative relation between voucher use and negative reciprocity suggests that workers who are more negatively reciprocal perceive the voucher as an HR tool for outplacement. Further, we find that voucher use positively affects worker employability awareness and willingness to train. Remarkably, participation in non voucher training shows little relation to personality traits. From a human resources (HR) perspective, this finding suggests that by employing a voucher scheme, the firm makes training participation more dependent on employee personality and individual characteristics instead of the HR development strategy of the firm.

Keywords: employability; voucher; training; human resource development; personality traits

JEL Classification: J24; M53

I. Introduction

Various studies show that worker employability is threatened by both the globalization of product and service markets and the skills-biased technological change (e.g. Feenstra and Hanson, 1996; Strauss-Kahn, 2004; Geishecker, 2006). Conversely, training has been shown to increase worker employability (e.g. Groot and

Maassen van den Brink, 2000; Sanders and De Grip, 2004). In turn, increasing employability is shown to have positive effects on worker careers and is crucial for maintaining firms’ competitive advantage (Van der Heijde and Van der Heijden, 2006). For these reasons, firms may consider encouraging their workforce to participate in training. Voucher schemes are one instrument designed to stimulate worker participation in training

*Corresponding author. E-mail: r.gerards@maastrichtuniversity.nl

and are used in numerous firms (Van Breugel *et al.*, 2011).

This article examines one firm's training voucher scheme. The voucher scheme we analyse is run by Philips Electronics Netherlands and is called Employability miles or E-miles. On 1 January 2009, all employees received a voucher with a face value of 1000 E-miles, regardless of their job or contract. These vouchers could be used for participation in a restricted number of training courses that aim to stimulate employees to develop a more active attitude toward their own employability, that is to increase their 'employability awareness'. The vouchers could not be used for any other training courses. Workers could redeem their voucher only in the 2009 calendar year. The voucher expired on 31 December 2009. Using panel data from two surveys of the firm's workforce, this article analyses (1) which workers use the vouchers and (2) whether voucher use increases worker employability awareness and their willingness to participate in further training.

We first examine which workers use their vouchers. Building on the existing literature, we focus on the role of personality traits (e.g. Leuven *et al.*, 2005) and personal characteristics (e.g. Arulampalam *et al.*, 2004). Our data include information not only on voucher use, but also on participation in other (regular) training courses not included in the voucher scheme (non voucher training). Therefore, we also analyse which workers participate in non voucher training, and we use this as a benchmark for our results with regard to the use of the training vouchers.

We find that voucher use is related to personality traits as well as to other personal characteristics. In particular, a worker's ambitions, goal setting and education level are positively related to voucher use. In addition, workers with longer tenure spend their vouchers more often. Conversely, workers with higher self-image and negative reciprocity spend their vouchers less often. The negative relation between voucher use and negative reciprocity is alarming from the firm's perspective, since it suggests that workers with greater negative reciprocity perceive the voucher as a threat to their job security rather than an encouragement to improve their employability. Remarkably, participation in non voucher training is only minimally related to personality traits. From a human resources (HR) perspective, this suggests that by employing a voucher scheme, the firm makes training participation more dependent on employee personality and individual characteristics. This enables the firm to reveal the ambitions of its workforce.

Next, we analyse whether workers who use their vouchers show increased employability awareness and a higher willingness to train compared to workers who did not use their vouchers. We measure workers' employability awareness and willingness to train via several survey questions for which we compare the outcomes between

the two survey moments. We find that voucher use positively affects worker employability awareness and worker willingness to train.

The remainder of this article is structured as follows. Section II discusses three relevant strands of the literature: the effects of voucher schemes, the relation between personality traits and training and the incidence of training. Building on this literature, we formulate several hypotheses that guide our empirical analysis. Section III presents our data and the details of the particular voucher scheme we analyse. This includes information on the questions we use to measure worker employability awareness and willingness to train. Section IV presents the results of our empirical analyses and relates the results to our hypotheses. Section V sets forth our conclusions.

II. Literature

Voucher schemes

Messer and Wolter (2009) conducted an experiment in which 2437 randomly selected Swiss citizens received an adult education voucher. They find a redemption rate of 18.4% and that voucher redemption occurs mainly among more highly educated females. On the basis of the same data used by Messer and Wolter (2009), Schwerdt *et al.* (2011) analyse the effect of voucher use on earnings and employment. However, these authors find no significant effects.

Van der Steeg *et al.* (2010) examine a training voucher scheme for teachers in the Netherlands. In line with Messer and Wolter (2009), they also find that the introduction of a voucher scheme has a limited impact on training participation. Out of every 10 vouchers, only one is used for a training course that would not have been taken without the voucher.

The analysis of the voucher scheme described in this article differs slightly from those in the above-mentioned studies. In this article, the main focus is on two questions: (1) which personality traits and personal characteristics of workers are related to voucher use and (2) do workers who redeem their vouchers actually perform differently with regard to the desired outcomes for the variables of the voucher scheme (i.e. worker employability awareness and worker willingness to train)? Since the training courses offered under the voucher scheme are designed to increase workers' employability awareness, we expect that voucher users improve their employability awareness compared to those who did not use their vouchers (*hypothesis 1*). Similarly, we expect a positive relation between voucher use and worker willingness to train (*hypothesis 2*).

Personality traits and training participation

There is a large body of theoretical and empirical literature on the incidence of training and whether workers or firms bear its costs. Standard human capital theory predicts that firms will not invest in general training because workers may leave the firm after receiving training (Becker, 1962). However, more recent literature provides various theoretical explanations for firm investment in general training from the perspective of human capital theory (e.g. Stevens, 1994; Acemoglu and Pischke, 1998, 1999a, b; Lazear, 2009; Booth and Katic, 2011) or social exchange theory (Koster *et al.*, 2011). One departure from standard theory focuses on the role of personality traits in training participation. Building on the literature in this field, our analysis includes various personality traits, ranging from reciprocal feelings to career ambition.^{1,2}

Leuven *et al.* (2005) are among the first investigators to introduce reciprocity in the empirical training literature. They base their definition of reciprocity on that of Fehr and Gächter (2000), who define it as an individual's response to a friendly action as 'frequently much nicer and much more cooperative than predicted by the self-interested model' (p. 159). The same holds for unfriendly actions, to which reciprocal individuals respond in a manner that is much more 'nasty and even brutal' (p. 159) than standard theory would predict. Positive reciprocity refers to cooperative responses, while negative reciprocity refers to retaliatory responses (Fehr and Gächter, 2000). The main finding of Leuven *et al.* (2005) is that workers who are driven by positive reciprocal motives are more likely to participate in training. Building on these findings, we expect that positive reciprocity is positively related to the use of vouchers. In addition, we expect that negative reciprocity is negatively related to voucher use. Since the voucher scheme was introduced in the midst of the global financial crisis and Philips Netherlands has undergone a number of large-scale reorganizations, workers may have perceived the employability voucher as a threat. Workers who are more driven by negative reciprocal behaviour may respond to this perceived threat by refusing to use their vouchers.

Individuals with an internal locus of control share the opinion that their own successes and failures are attributable

to their own actions and decisions. Noe (1986) argues that people with an internal locus of control feel that they can control their environment. This is the reason that such individuals take opportunities that may increase their probability of receiving rewards such as promotions, pay increases or recognition (Noe, 1986, p. 739). Noe (1986) finds that workers with an internal locus of control

participate in training more often. Colquitt *et al.* (2000) confirm this finding. Therefore, our expectation is that workers with a more internal locus of control are more likely to use their vouchers.

Anxiety is a measure of whether individuals fear situations with which they are not familiar. Fear of exams is a typical factor for which individuals with anxiety score high (Fouarge *et al.*, 2013). Anxiety is found to be negatively related to worker motivation to learn (Webster and Martocchio, 1993; Colquitt *et al.*, 2000), training participation and the level of regret individuals show in the choices they make (Borghans *et al.*, 2006). Based on these results, we expect that anxiety is negatively related to voucher use.

Self-confidence is the extent to which individuals believe in themselves. Bénabou and Tirole (2002) conclude that 'an individual's confidence in his abilities can help him to undertake more ambitious goals' (p. 872). Borghans *et al.* (2006) find that more highly educated individuals show a greater level of self-confidence. This effect may be self-reinforcing since another of these authors' findings is that self-confident individuals are more willing to participate in training and consequently participate more. Hence, we expect that self-confidence is positively related to voucher use.

Self-image is the extent to which individuals are able to reflect on who they are. Borghans *et al.* (2006) argue that individuals who have a positive self-image are better able to determine whether training is useful to them. However, this could affect workers' willingness to train either positively (if they think a particular course of training is useful to them) or negatively (if they think they do not need training).

We measure workers' imaginations by asking how they imagine their life will be in 15 years. Individuals with higher levels of imagination may also have a better picture of how training can contribute to this envisioned future. We therefore expect that imagination is positively related to voucher use.

Facteau *et al.* (1995) find a relation between planning behaviour and training motivation. Individuals with a high level of goal setting indicate that they set achievement goals. To set goals, individuals must first assess their current situation and compare it to their future desired situation. They must be aware of their strengths and weaknesses before they can set relevant goals. Individuals may be more eager to participate in training because they know it can improve their weaknesses, leading to a greater willingness to participate (Colquitt *et al.*, 2000). Hence, we expect that goal setting is positively related to voucher use.

¹ Our selection of personality traits builds on the results of a meta-analysis by Colquitt *et al.* (2000).

² The survey questions we use to measure workers' personality traits are listed in the Appendix.

Career ambition can also be a driver of training participation (Colquitt *et al.*, 2000). We measure workers' career ambition by the extent to which they picture themselves switching to a different firm within 5 years. An ambitious career attitude means that the individual wishes to develop and probably has a clear view of the role that training can have in this respect (e.g. Mathieu *et al.*, 1993; Facticeau *et al.*, 1995). Therefore, we expect that career ambition is positively related to voucher use.

The above overview of the literature expresses the direction in which we expect each of the several personality traits to affect voucher use. We thus set forth the hypothesis that each personality trait affects voucher use in the expected direction (*hypothesis 3*).

Personal characteristics and training participation

The literature on the incidence and duration of training generally finds that younger and more highly educated workers are more likely to participate in training (Bassanini *et al.*, 2007). Therefore, we expect that worker age is negatively related and education is positively related to voucher use.

With respect to gender, the results from the literature are mixed. Studies in the 1980s and 1990s often find that women report a higher training incidence than men, but these courses were short in duration, leading to the conclusion that women receive less training (e.g. Altonji and Spletzer, 1991). However, more recently, Bassanini *et al.* (2007) find that women are more likely to participate in training and that this includes training of longer duration. O'Halloran (2008), however, shows results that are in line with the literature of the 1980s and 1990s; that is, women have a higher incidence of training but the duration of this training is shorter. Finally, Dieckhoff and Steiber (2011) find that women receive less training than men. Messer and Wolter (2009) find that women are more likely to use their vouchers than men. Moreover, the courses offered through the E-miles voucher scheme that we analyse are very short (maximum of one day) and much shorter than the average for non voucher training. Therefore, we expect that women are more likely to use their vouchers than men.

With respect to the relation between worker tenure and training participation, the findings from the literature are also mixed. Loewenstein and Spletzer (1997) and Croce

and Tancioni (2007) find that training increases with tenure. However, Frazis *et al.* (2000) find no significant effect of tenure on the probability of training, whereas Bassanini *et al.* (2007) find a U-shaped relation between tenure and training. These studies evaluate the relation between training and tenure as a decision concerning to whom the firm wants to offer training opportunities. However, in our study, the firm supplied a voucher to all employees, guaranteeing a training supply. As a result, the relation between voucher use and tenure can be explained only from the perspective of the workers themselves. We expect that tenure is positively related to voucher use because workers with short tenure have been hired more recently and have therefore recently been active in the job search process. This provides them 'confirmation' of their employability, whereas those with longer tenure may be more uncertain about their employability and may therefore be more eager to use their E-miles vouchers.

The overview of the literature above expresses the direction in which we expect each personal characteristic to affect voucher use. We hypothesize that each personal characteristic affects the use of vouchers in the expected direction (*hypothesis 4*).

Schematic overview

Figure 1 summarizes the structure of our analysis and hypotheses. All dependent variables are shown in italics. All dependent variables are either rank order outcomes or 0/1 dummies. We use ordered logit or logit estimators, which enables us to report odds ratios, providing an enhanced interpretation of the results. Using ordered probit or probit leads to very similar results that do not change any interpretation or conclusion. In addition, we estimate a treatment effects model to correct for possible endogeneity of voucher use.

III. Data

Our data come from two surveys that we conducted in cooperation with Philips Netherlands. The first survey took place in December 2008, before the introduction of the voucher scheme. At that time, employees were not yet informed about the introduction of the voucher scheme. Therefore, this first survey establishes a baseline. The

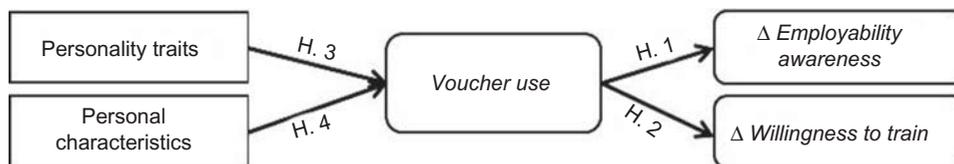

Fig. 1. Structure of the empirical analysis and hypotheses

second survey took place in February 2010, that is just after the expiration date of the 2009 voucher. Both surveys addressed various aspects of the training, personality traits, the workplace and voucher use. Most survey questions were yes/no or a five-point Likert scale, allowing workers to indicate to what extent they (dis-)agree with a given statement. Both surveys were conducted among a randomly drawn sample of 2500 regular employees. The response rate in both surveys was 38%. Personal characteristics were collected in the first survey. To be able to use these personal characteristics in our analysis, only those individuals who responded to both surveys were retained in our sample. This leads to a sample of 648 individuals who responded to both surveys.³ With respect to several observable characteristics, these respondents are representative of the workforce of Philips Netherlands.⁴

Descriptives

Table 1 provides an overview of the training courses offered through the voucher scheme and the amount of E-miles needed per course. Before the start of the voucher scheme, all employees received information on the

voucher via e-mail. This e-mail also included information about the various training courses offered. Enrolment for training took place via online registration. The *E-check course* requires all the E-miles a worker has received; the self-insight training is also relatively expensive. *Employability advice*, *career pit-stop* and *route planner* require fewer E-miles. Workers are allowed to spend their voucher on more than one training course.

From the sample of 648 employees, 123 (19%) used their vouchers. This is a rather low percentage but in line with the results from the studies discussed in Section II. For respondents who did not use their vouchers, the most important single reason given was ‘a lack of time’ (22%). Other reasons included ‘no interesting products in E-miles offer’ (16%) and ‘never heard of E-miles’ (11%). Figure 2 depicts the share of vouchers spent on the various training courses in 2009. More than half of the vouchers were spent on the most expensive training course, E-check, requiring the entire amount of E-miles. Around 30% of workers spent their voucher on the self-insight course (the second most expensive training course) and almost one-quarter of voucher users spent their vouchers on the

Table 1. Voucher training courses

Training	Content	E-miles required
E(mployability)-check	2 hour computer test, 1 hour individual evaluation with career counsellor	1000
Self-insight	30 minutes computer test, 1 hour individual evaluation with career counsellor	700
Employability advice	One hour individual consultation with career counsellor	350
Career pit-stop	Workshop on career development, 4 hours	300
Route planner	Competence game, 4 hours	300

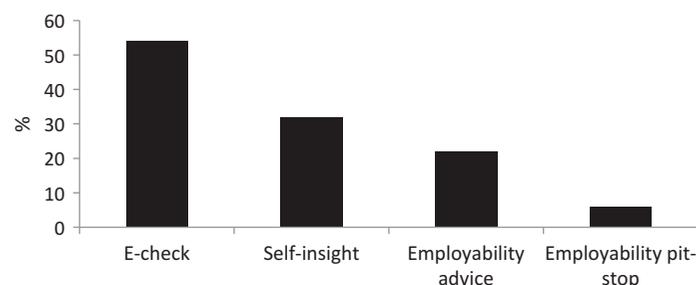

Fig. 2. Voucher training taken

³ There could be a bias in our results, which are based on our sample of 648 individuals who responded to both surveys, because the sample only includes those who ‘stayed’ with Philips. However, by analysing e-mail server bounces, we identified only 32 persons as possible ‘leavers’ because their e-mail address returned a server bounce at the second survey. T-tests on several key personal characteristics and survey questions show that these 32 individuals have similar characteristics and give similar answers to key questions as those respondents who stayed at Philips.

⁴ The average age of respondents is 44 and the average age of Philips’ total workforce is 43. In both cases, more than 60% of the population is male. Further, respondents have 12 years of education on average, and Philips’ total workforce has 13 years of education on average. Finally, respondents have an average of 17 years of tenure, whereas this figure is 13 years for the total Philips population. However, the SD of our sample’s tenure is 11. So the sample mean may not be statistically different from the population mean. Since we do not have data on the population SD, we cannot test this.

employability advice. The career pit-stop was used by only 6%. One-third of the workers who used their vouchers purchased only one of the low-priced training courses, thus not spending all their E-miles. Whereas voucher use includes only these five short-duration training courses, non voucher training mainly refers to short and long-duration courses on vocational skills, computer/ICT skills, time-management and communication training.

Panels A and B of Fig. 3 show voucher use by age and tenure, respectively. Younger workers and workers with shorter tenure have a relatively high voucher redemption rate. Further, voucher use appears to be far more popular among female workers. Although only 15.5% of male workers used their vouchers, almost 26% of female workers spent their E-miles.

Table 2 shows the means and SDs of the variables included in the empirical analyses. The remainder of this section discusses the descriptive statistics for the variables used in our analysis.

Dependent variables

Voucher use and participation in non voucher training was measured by straightforward yes/no questions. Employability awareness was assessed by asking the

workers to reply to a number of statements on a five-point Likert scale. These statements are as follows:

- (1) I myself am responsible for my future development.
- (2) I have a clear view of how I want to develop myself in the years to come.
- (3) I know what I need to do to achieve my goals at work.
- (4) Would you like to have a new job within Philips in the next five years?
- (5) Would you like to have a new job outside Philips in the next five years?

The term employability can be interpreted in many ways (see De Grip *et al.*, (2004) for a history of the term) we here define our interpretation of employability as follows (De Grip *et al.*, 2004, p. 216):

'Employability refers to the capacity and willingness of workers to remain attractive for the labour market (supply factors) by reacting to and anticipating changes in tasks and work environment (demand factors), facilitated by the human resource development instruments available to them (institutions).

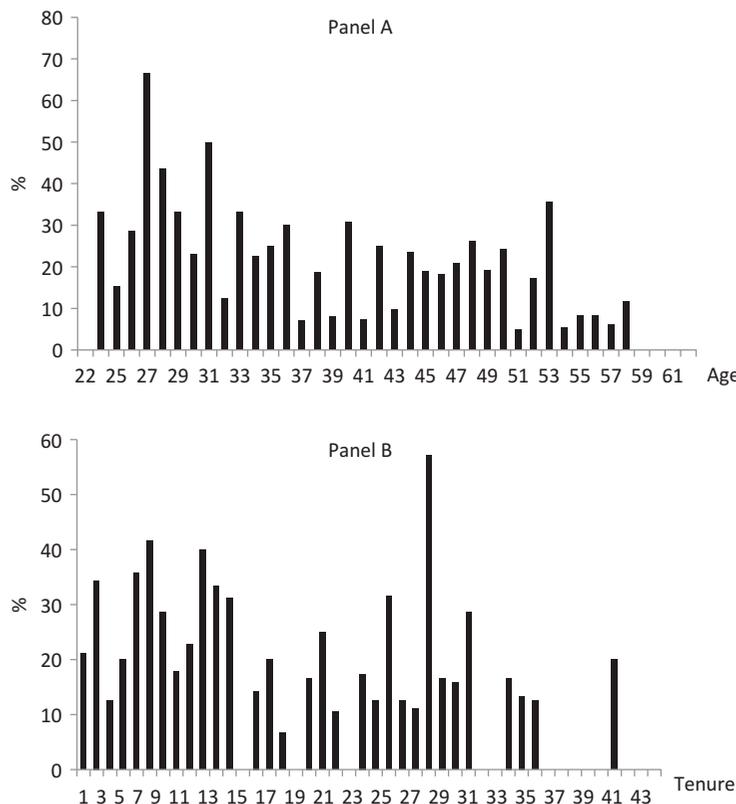

Fig. 3. Voucher use by age (Panel A) and tenure (Panel B)

Notes: ^aPersonality traits are assumed to remain constant over time. Even though this is not necessarily the case, many economists and psychologists use this assumption (see, e.g., Borghans *et al.*, 2008).

^bPercentage of workers who report this instrument is used/offered by their manager/outlet.

^cPercentage of workers who work in this sector.

This definition includes two dimensions: worker willingness and worker capacity: ‘The first – *willingness* – measures peoples’ desire to engage in activities that keep them attractive on the labour market. The second – *capacity* – is concerned with the power to develop one’s position on the labour market’ (De Grip *et al.*, 2004, p. 217).

These two dimensions can be further broken down into a number of indicators of employability (Bolweg and Maenhout, 1995; De Grip *et al.*, 2004). All five statements we use to measure employability awareness relate to one of the indicators of employability. Statements 1 and 2 refer to the ‘capacity to participate in training’, statement 3 to the ‘capacity to be mobile’ and statements 4 and 5 to the ‘willingness to be mobile’. The more positively workers respond to each of these statements, the more active their attitude is and the higher we assess their employability awareness. We measure workers’ willingness to train (also one of the indicators of employability) via a question that

attempts to indicate whether workers want to spend leisure time on training participation:

If it were possible to take a 1-year training course for which you have to study 8 hours per week (in your leisure time) and in return you might get a 5% salary increase, would you take the training?

Independent variables

The personality traits listed in Table 2 are measured on a five-point Likert scale. A higher score means that the respondent exhibits the corresponding personality trait to a greater extent. All personality traits are measured using three questions. Our analysis uses standard factors of these variables when Cronbach’s alpha was sufficiently high (over 0.7, based on Peterson, 1994). The Appendix lists all questions per construct and, where applicable, Cronbach’s alpha. For constructs for which Cronbach’s alpha was too low, only one of the questions was used to

represent that particular personality trait. In these cases, we used the question with the most prominent results. Table 2 shows that respondents have, on average, a relatively high score (a mean around three out of five or higher) for being able to create a self-image, being able to imagine the future, positive reciprocity and goal setting. Conversely, respondents have, on average, relatively low levels of anxiety, negative reciprocity and career ambition. The relatively low career ambition may be related to the fact that Philips is commonly viewed as one of the most popular employers in the Netherlands, combined with the fact that our measure of career ambition measures only external ambition (the ambition to continue one's career outside Philips). Since our sample already works with Philips, they may already be very content with this achievement, which may relate to the lower (external) career ambition.

Several personal characteristics are included in the analyses. Respondents were asked to report their age, tenure, gender and education level, and we include age-squared and tenure-squared. We measure respondents' level of education by converting Dutch educational attainment levels to the related nominal years of education. The average age of all respondents is 44, and the sample contains more male than female respondents. Respondents have, on average, 12 years of education and an average tenure of 17 years. This set of averages

on personal characteristics may provide a further clue about the relatively low career ambition overall. At middle age with substantial tenure and no higher education, workers may simply not have much ambition remaining. Employing many workers with these characteristics makes the relevance of the E-miles program and its attention to employability relatively higher than if the average age and tenure were much lower and the level of education higher.

We control for several factors that may affect the dependent variable. These control variables are HR practices and the sector in which respondents work. With regard to HR practices, respondents were asked to indicate whether a particular practice had been used by their manager or department (yes/no). Table 2 includes the firm's HR practices.

IV. Results

Which workers use their vouchers?

Table 3 shows a series of binomial logit estimations on the use of E-miles vouchers. Column 1 shows the results of an estimation without the control variables, whereas column 2 includes sector dummies and column 3 includes both the

sector dummies and the various HR practices. The final column reports the odds ratios for variables that have significant coefficients. The odds ratio shows the factor with which the probability of voucher use increases, as the value of the respective independent variable increases by one unit. The table shows that the personality traits locus of control, goal setting and career ambition are positively related to the use of vouchers. These results confirm our expectations formulated in the section 'Personality traits and training participation' with regard to these variables. The odds ratio for career ambition shows that if career ambition increases by one unit, the probability of voucher use increases by 1.44. All other odds ratios can be interpreted similarly. It is not surprising that workers with higher career ambitions are more likely to use the opportunity that E-miles provide to assess their current and future employability. The negative relation between negative reciprocity and voucher use confirms our expectation. The weakly significant negative coefficient for self-image suggests that workers who have a better self-image less often think they need to improve their employability awareness. Most personal characteristics included in the analyses do not significantly contribute to voucher use. Only education level shows a highly significant relation to voucher use, confirming our expectation. For tenure, we also find a weakly significant positive relation to voucher use. However, voucher use is not significantly related to worker age. Of the included sets of HR control variables,

only the mid-year review is positively significant. Workers who had a mid-year review used their voucher more often in the second half of the year than those who did not have a mid-year review. This suggests that the mid-year review was possibly used to remind those who had not used their voucher yet to do so. There were also some differences between sectors. Workers in the lighting sector were more prone to use their vouchers than workers in the consumer lifestyle sector, reflecting differences in culture between these sectors.

Table 4 shows a series of estimations on worker participation in non voucher training. To compare these outcomes with those from voucher use in Table 3, we use information only from the second survey. Of all the personality traits, only goal setting is significant, whereas negative reciprocity is only weakly significant when all control variables are included. From the set of personal characteristics, one highly significant result emerges: Women are less likely to participate in non voucher training than men. None of the control variables have a significant impact on the probability of participation in non voucher training.

Comparing the results from Tables 3 and 4, we observe that both personality traits and personal characteristics play a far more important role in voucher use than in non voucher training. Locus of control, self-image, negative reciprocity, goal setting and career ambition all relate to voucher use across the three estimations, whereas only goal setting is consistently

significant with regard to participation in non voucher training. Further, the estimation results show that women are less likely than men to participate in non voucher training. Other personal characteristics such as education and tenure also relate to voucher use, whereas they do not relate to participation in non voucher training. From an HR perspective, these differences suggest that by employing a voucher scheme, the firm makes training participation more dependent on employee personality and individual characteristics. Section V elaborates on this interpretation. Although not reported in a table, we also ran the estimations from Table 4 using observations from both surveys while clustering on the individual. Here we find that the HR practices of a personal development plan and a mid-year review are significantly positively related to participation in non voucher training. This suggests that participation in non voucher training is more likely a decision made by the line manager or jointly made by the manager and worker and formalized in a personal development plan or mid-year review.

Does voucher use increase employability awareness?

Table 5 shows the estimation results of ordered logit regressions on the relation between voucher use and changes ($t_2 - t_1$) in five indicators of worker employability awareness and willingness to train. In all regressions, the dependent variable measures the difference in employability awareness or willingness to train between December 2008, before the introduction of the voucher system, and February 2010, immediately after the expiration date of the vouchers. For each dependent $t_2 - t_1$ change variable, we ran an ordered logit regression, including various sets of controls. Additional regressions with varying sets of controls provide robust results. By analyzing the difference between t_2 and t_1 , we correct for selection effects that may otherwise occur with regard to the initial level of the dependent variable.

Table 5 shows that workers who used their vouchers experienced a positive *change* in their employability awareness compared to workers who did not redeem their vouchers. This holds for four components of employability awareness: responsibility for one's future development, knowing what to do to achieve goals at work, having a clear view of how to develop in the next few years and aspiring to a new job with Philips in the next five years. The variable measuring workers' ambition to work outside Philips within the next five years is not significant. With four out of five variables being significant, these results largely confirm hypothesis 1. However, Table 5 also shows that those who used their vouchers did not show a significantly different change in their willingness to train than those who did not use their vouchers. Thus, hypothesis 2 cannot be confirmed on the basis of this estimation.

The estimations reported in Table 5 correct for selection effects that may occur with respect to the initial level of the dependent variable. To correct for the possibility of time-varying unobserved variables that may lead to selection bias, we use a treatment effects model that estimates a selection equation for voucher use and a regression equation of the effect of voucher use on the relevant $t_2 - t_1$ change variable. This model is derived by Maddala (1983) for cases with endogenous binary treatment variables and continuous outcome variables. More recent literature on its application includes Cong and Drukker (2000), Greene (2000), Guo and Fraser (2010), Antonakis *et al.* (2010) and Antonakis *et al.* (2012). The selection equation estimates voucher use with the same variables as in Table 3: personality traits, personal characteristics, the sector and HR practices. The outcomes are the same as those in Table 3.⁵ The regression equation estimates the effect of voucher use on the relevant dependent variable. Table 6 reports the results of these treatment effect estimations. The likelihood ratio test of independent equations rejects the null hypothesis of independence for all estimations, confirming the endogeneity problem and the need to use this treatment effects model (Guo and Fraser, 2010). Therefore, this is our preferred estimator.

The estimation results show that voucher use significantly affects all measures of employability awareness and the willingness to train. The significant positive coefficients for voucher use in columns 1 to 3 of Table 6 confirm the results in Table 5. The coefficient for aspiring to a new job with Philips in the next five years turns out to be negative and significant in the treatment effects model, whereas it is positive and weakly significant in the ordered logit estimates. The coefficient for aspiring to a new job in a different firm in the next five years is now significant and positive, whereas it is insignificant in Table 5. The negative significant coefficient for ‘within Philips mobility ambition’ and the positive coefficient for ‘outside Philips mobility ambition’ shows that voucher use increases firm external employability awareness at the cost of internal mobility ambitions. These outcomes further confirm hypothesis 1. Finally, column 6 of Table 6 shows that voucher use is positively related to worker willingness to train, confirming hypothesis 2.

V. Discussion and Conclusions

This article analyses a firm’s training voucher scheme to determine (1) which workers use their vouchers and (2)

⁵ Only the size of the coefficient differs, since the treatment effects model uses a probit instead of a logit estimator for the first stage.

whether the vouchers increase workers' employability awareness and willingness to participate in further training. Overall, voucher redemption is low, at 19%, which is similar to the findings of other studies on voucher schemes. We find that voucher use is related to various personality traits and personal characteristics. Voucher use is higher for workers with a more internal locus of control, as well as higher levels of goal setting, career ambition, education and tenure. In particular, goal setting and career ambition, which embody the ability to reflect on the future, have the highest odds ratios. Moreover, we find that workers with higher levels of self-image and negative reciprocity use their vouchers less often. The negative relation between self-image and voucher use shows that workers with a lower self-image are more likely to use their vouchers, which is positive, since the voucher training courses are designed to increase worker employability awareness and, as such, should aid in improving worker self-image. However, the negative relation between voucher use and negative reciprocity is alarming from the firm's perspective, since this finding suggests that workers who behave with greater negative reciprocity perceive the voucher as a threat. Since the timing of the voucher scheme coincided with the global financial crisis, workers with greater negative reciprocity may have perceived the employability vouchers as a signal that the firm wanted to reduce its workforce.

One might wonder whether our analyses could suffer from reverse causality when voucher use would affect a worker's personality traits. However, we do not see that this could occur. First, recent literature clearly shows that personality traits are remarkably stable and are not influenced even by major life events (see for instance Cobb-Clark and Schurer, 2012, 2013 and Specht *et al.*, 2011). Second, we derived the information on personality traits in the survey, which was held before the year the voucher could be used.

We benchmark the findings with regard to voucher use against an analysis of worker participation in non voucher training. Contrary to voucher use, we find that, apart from goal setting, participation in non voucher training is not significantly related to personality traits or personal characteristics. We conclude that the more significant role of personality traits and personal characteristics in voucher use is a result of the design of the voucher system. All workers were given a voucher and the firm thereby guaranteed the opportunity to train for all workers. The workers decided for themselves whether they would use their vouchers. Since this was their own individual decision, their personalities and personal backgrounds affected their decisions. From an HR perspective, this suggests that by employing a voucher scheme, the firm makes training participation more dependent on employee personality and individual characteristics. This enables the firm to reveal the ambitions of its workforce. Conversely, participation in

non voucher training is determined by management decision making or a joint decision of the worker and a manager. This decision depends particularly on available time, budget and return on investment. The latter factor is underscored by the positive relation between participation in non voucher training and the use of HR practices such as personal development plans and mid-year reviews. These HR practices are typically used to formalize agreements between workers and management about workers' work-related development and the role training has in this development.

Furthermore, we find that the voucher scheme positively affects the employability awareness of workers who used their vouchers. We find these effects by analyzing the development of various indicators of worker employability awareness between the two surveys. All indicators show that the employability awareness of workers who used their vouchers significantly improves compared to those who did not use their vouchers. Moreover, the analysis shows that workers who used their vouchers show a significantly positive change in their willingness to train compared to workers who did not use their vouchers.

Overall, the voucher scheme appears to achieve the goal it was designed for: it significantly increases employability awareness among those who spent their vouchers. However, our results also show that the workers who are more likely to use their vouchers are those who already had higher levels of ambition and education, an internal locus of control and a lower level of negative reciprocity. One can argue that workers with these traits and characteristics are those who have relatively less to gain from employability training because they are already better equipped to withstand future threats to their employability than workers who have less education and ambition, an external locus of control and a higher level of negative reciprocity. As we argue above, workers who are more driven by negative reciprocal behaviour may perceive the voucher as a threat to their employability, whereas the voucher was intended to be a stepping stone to improve workers' employability. This suggests that voucher redemption can be further optimized if the voucher system and the communications around it are designed to minimize the scope within which voucher recipients can view the system with suspicion.

Appendix: Survey Questions

Table A1. Survey questions corresponding with variables*

Variable	Question	Cron. Alpha
<i>Personality traits</i>		
Locus of control	– Setbacks can usually be blamed on other people.	
Self-confidence	– I have the tendency to think someone else is better than I am.	
Anxiety	– I am scared of going to places where I have not been before.	
Self-image	– Generally, I have a clear picture of who I am and what I am capable of.	
Imagination	– Sometimes I imagine what my life will look like in 15 years.	
Negative reciprocity	– If someone treats me unfair, I will do anything I can to take revenge. – If I feel offended by someone, I will do the same to him.	0.81
Positive reciprocity	– If someone puts me in a unfavourable position, I will do the same to him. – When someone pleases me, I am willing to give something in return. – I always try to help someone who has helped out in the past.	0.78
Career ambition	– I am willing to provide effort to help someone who has helped me out in the past. – Would you like to work for a different company in five years from now?	0.75
Goal setting	– Do you think you will work for a different firm in five years from now? – I set goals in what I want to achieve.	
<i>Employability awareness</i>		
Responsibility for future development	– I myself am responsible for my future development.	
Clarity of approach	– I know what I need to do to achieve my goals at work.	
Image of future self-development	– I have a clear view of how I want to develop myself in the next years.	
New job within five years	– Would you like to have a new job within Philips in the next five years?	
<i>Willingness to train</i>	– If it were possible to take a 1-year training course for which you have to study 8 hours per week (in your leisure time) and in return you might get a 5% salary increase, would you take the training?	
<i>Control variables</i>		
HR practices	Does the Philips outlet you work in use the following HR practices? (yes/no)	
–Assessment interviews	– Assessment interviews	
–Personal dev. plan	– Assistance in making a personal development plan	
–Regular feedback	– I get regular feedback from my direct superior	
–Task/job rotation	– The option of task/job rotation exists	
–Mid-year review	– Development-interviews (mid-year reviews) are being held	

Notes: All questions in this table (except HR practices) are answered on a five-point Likert scale. The remaining (straightforward) questions asked include personal characteristics: age, gender, tenure and education level as well as the sector in which employees work: consumer lifestyle, healthcare, lighting or other.

*For some personality traits, we report only one question in this table. In these cases, the Cronbach's alpha turned out relatively low and we decided for our analyses to use only the question reported in the table for that personality trait.
